for differences between the diameters as measured on the casts and on the original. The casts were, on average, significantly larger than the original (n = 80 measurements; average difference = 0.42 ± 0.05 %; t = 8.589).

The two techniques were comparable in cost for materials, but photography required a large initial outlay for camera and flash. In 1984, materials for each finished photographic record cost ca. 80 cents US, as opposed to approximately 60 cents US for a finished cast. When the total costs of a field season are tallied, the additional expense per turtle for either photographs or casts is small.

In general, each type of record presented advantages and disadvantages both for making and for using the records. Photography was more portable, and required less time in the field, and finished prints were easier to use than were casts. The casts, however, provided three-dimensional detail with better resolution than the photographs (Fig. 3). In addition, the photographs were developed weeks later, with no possibility of returning to re-photograph. The cast molds were ready to be cast immediately, and if required, could be repeated. Growth lines that could not be seen on photographs were visible on casts when illuminated from a low angle, to throw shadows. In addition, the casts themselves can be rephotographed as needed.

Both photographs and casts have proven useful in field studies (Galbraith 1986). Photographs were adequate for enumeration of growth lines, and for making measurements to estimate missing growth lines on turtles with worn scutes. The fine resolution of the casts enabled comparisons under magnification of specific recent growth lines between years on adult turtles. In general, permanent records of growth lines provided by photographic or casting procedures will allow direct inter-year comparisons and repeated observations under laboratory conditions for the construction of confidence limits around age estimates, and will provide ample reward for the small investment of time and funds required.

ACKNOWLEDGEMENTS

The authors thank Drs. D. E. Snider, D.D.S, and A. R. Vano, D.D.S., for their assistance during development of the casting technique. We thank E. G. Nancekivell and three anonymous reviewers for criticisms of earlier drafts of this paper. This study was funded by Natural Sciences and Engineering Research Council, Canada, Grant A5990 to R. J. Brooks.

LIFE HISTORY NOTES

See Herp. Review 18(1) for author's instructions.

ANURA

***PLECTROHYLA GUATEMALENSIS*. REPRODUCTION.** Adult males of *Plectrohyla guatemalensis* lack vocal slits and a vocal sac and thus have been presumed to be mute (Duellman 1970. Monogr. Mus. Nat. Hist., Univ. Kansas No. 1, vol. 1 and 2). However, we have collected calling adult males of this species at several localities in Honduras. The call consists of a single low pitched note best described as a grunt which is repeated at intervals of about two min. Males call from concealed positions and have been collected while calling from within a vertical crack in a boulder (LDW 6376, Depto. Copán; Quebrada Grande, 1370 m), inside an arboreal bromeliad ca. 5 m above the ground (LDW 6183. Depto. Ocotepeque; El Chagüitón, 1870 m), and from a hollow portion of a slender tree ca. 6 m above the ground (LDW 8370. Depto. Francisco Morazán; Cerro Cantagallo, 1900 m). At the latter locality, at 1840 m, several males were heard calling from the underground root systems of trees and shrubs growing along the banks of and within a small stream. While trying to locate one of these calling males, we discovered a single clutch of eggs, presumably of this species, within one of these root systems. The eggs were in contact with the bottom of the shallow stream and were adhered to the roots of a shrub. There were 240 eggs in the clutch (LDW 6671) each with a diameter of about 3.4 mm. Two other stream-breeding frogs (*Hyla spinipollex* and *H. salvadorensis*) also occur at this locality. However, our eggs were considerably larger than those reported for the smaller *H. spinipollex* and related species (Duellman 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:297-349) and likewise were larger than those to be expected from the even smaller *H. salvadorensis*.

All of the above localities were alongside small, slow moving, and quiet montane streams in relatively level areas. The call was readily audible from distances of up to 5 m even though the sound was muffled by the nature of the calling position. The other Honduran localities where *P. guatemalensis* have been collected were along larger, fast moving, and "roaring" streams in areas of considerable relief. We have never heard this frog calling under such conditions and it is doubtful that the call, if present, could be heard by us above the noise created by these streams.

RANA SEPTENTRIONALIS (Mink Frog). **TERRESTRIAL ACTIVITY.** Hedeen (1986. Copeia 1986(1):239-244) notes that there are few published reports of terrestrial activity by *Rana septentrionalis*. He observed such activity in Minnesota at night, and concluded that "Mink frogs usually restrict their overland movements to periods of nocturnal precipitation." I report here a summary of terrestrial (including diurnal) activity of this species.

From 1979 to 1986. I collected on gravel roads through broad-leaved swamp forest, brushy marsh and cultivated fields in Limerick Forest, 4 km E Bishops Mills, Grenville Co., Ontario. During rainy fall nights I never found *R. septentrionalis* on the road before 13 October, but it was collected frequently after 13 October, representing 20% of the total ranids (66 of 328 specimens; five species) found on the road. Most of the frogs had empty digestive tracts, suggesting the overland movement was toward hibernating sites in flowing water.

At 0400 h of 13 June 1983, at a lake 3 km SE Postelnic Lake, Kenora Dist., Ontario, R.M. Rankin and I found a male *R. septentrionalis* (57 mm SVL (NMC 24466-3)) on a gravel roadway. We found others in a ditch-like channel in a peaty lakeshore marsh, but only the one on the road was active. The air was 24° C at 0100 h, lake water temperature 18° C at 1500 h, and there had been no rain for several days. At 1320 h, 18 September 1986, just E of the road to Holtyre, 16 km E of Matheson along Hwy 101, Cochrane Dist., Ontario, I found a thin, 49 mm SVL, 8.06 gm, male *R. septentrionalis* (NMC 28813) in the middle of the highway, 400 m from any water deeper than 10 cm roadside ditches in muskeg. A light rain was falling, and the air temperature was ca 12° C.

The National Museums of Canada catalogue files list nine additional collections of *R. septentrionalis* that were made on land at night or in puddles in roadways: Nova Scotia (15, 20, 21 Aug 1971); Gaspé, Quebec, (5 June 1971); eastern Ontario (11 Sept 1982, 6 Nov 1984); and Cochrane area, Ontario (12, 16 Aug 1972, 17 Sept 1986).

CAUDATA

NOTOPHTHALMUS VIRIDESCENS DORSALIS (Broken-striped newt). **BEHAVIOR.** Antipredator posturing has been documented in a variety of salamanders. Perhaps the most striking displays are the "unken" postures exhibited by salamandrids (Brodie 1977. Copeia 1977:523-535). Neill (Copeia 1955:61) observed antipredator posturing of adult *Notophthalmus viridescens louisianensis* in the dried beds of bottomland pools in Georgia when air temperatures were slightly above freezing. Because he had collected numerous adults and efts on other occasions that never assumed the unken posture, he postulated that the behavior only occurred when newts were chilled and unable to move quickly.

On 11 January 1987 I observed antiposturing behavior in *N. v. dorsalis*, 2.7 miles N of Wagram in Scotland County, North Carolina. Five pairs of amplexed aquatic adults were collected from a flooded burrow pit, and three terrestrial adults were found beneath cardboard boxes within 30 m of the pond margin. When initially uncovered, all three terrestrial adults assumed an unken posture. Fig. 1 shows two adults photographed at the site of capture immediately after the boxes were lifted. The posturing was similar to that described by Neill, except that the limbs of *N. v. dorsalis* were drawn inward rather than being flexed, the front toes were overlapped or crossed, and the animals rested on their tails and hindlimbs rather than their chests and forelimbs. Individuals maintained the unken

posture for 2-3 minutes before unfolding and assuming a normal posture. Air and water temperatures at the time were 7° C.

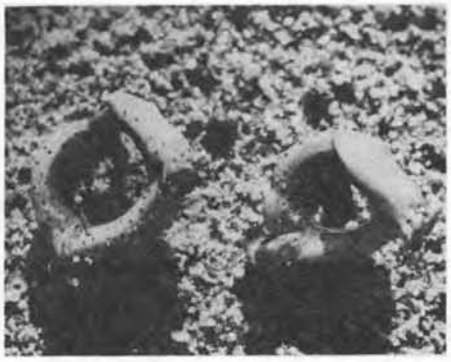

Figure 1. Antipredator posturing of two *Notophthalmus viridescens dorsalis from North Carolina.*

I prodded and pinched ten aquatic adults collected from the pond, but was unable to induce any antipredator posturing. Three terrestrial adults and five aquatic adults were taken to the laboratory, placed on wet sand collected from the borrow pit, and maintained at room temperature. After two hours, I attempted to induce posturing. All three terrestrial adults again assumed the posture seen in Fig. 1, while four of the five adults removed from the pond assumed a modified posture with the head flexed laterally, rather than mid-dorsally. This modified posture was similar to that of *Triturus alpestris* pictured by Brodie (op. cit. : p. 526), except that the limbs were drawn inward and the front toes were crossed. The following day when prodded, all but one of the terrestrial adults and all five aquatic adults assumed this modified posture rather than the posture in Fig. 1. Subsequent prodding every few days thereafter induced similar behavior.

My observations as well as Neill's suggest that antipredator posturing is commonplace in terrestrial adults that have left water and moved to land. Chilling obviously is not a requisite for posturing since terrestrial adults postured at room temperature. The rapid response of aquatic adults after being removed from water suggests that the switch to strong antipredator posturing upon leaving water is not hormonally-mediated. I have occasionally collected terrestrial adult *N. v. viridescens,* but have never observed antipredator posturing in this subspecies.

CHELONIA

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). **SIZE.** An exceptionally large male *Chelydra serpentina serpentina* was caught in northern Minnesota on 25 May 1986 by a fisherman in the Popple River at the north end of Squaw Lake, Itasca County. (NW¼ SE¼ Section 28 T149N R27W) The CL = 49.4 cm and was 40.7 cm in width. Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston 429 pp.) lists the record CL as 47.0 cm. No record of a larger specimen could be located. Mass of the turtle = 29.6 kg at the time of capture.

The turtle was purchased by the Minnesota Department of Natural Resources. It was displayed at the Itasca County Fair and the Minnesota State Fair. It was then tagged on the back of the carapace (B-7001) and double-notched on marginal 14. On 17 September 1986 it was released at the capture site.

Figure 1. Snapping turtle captured in northern Minnesota. Ruler on carapace measures 12 inches.

PSEUDEMYS TEXANA (Texas River Cooter). **SIZE MAXIMA.** Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 2nd Ed., Houghton-Mifflin Co., Boston. 429 pp.) lists 27.3 cm carapace length (CL) as the maximum known size for *Chrysemys concinna texana (=Pseudemys texana).* Here we report record sizes for this taxon in northcentral texas.

A large female *P. texana* (CL= 30.5 cm) was collected by G. Owen on 13 October 1985 in Throckmorton Co., 24.1 km E Throckmorton on TX 222. Another large female *P. texana* (CL= 29.7 cm) was collected by one of us (CTM) on 13 June 1987 in Johnson Co., 17.0 km NE Glen Rose Off US 67 on county rd. 1234. The former specimen increases the upper range of CL by 3.2 cm.

Voucher specimens are deposited in the University of Texas at Arlington Collection (UTA R-18692) and the Texas Cooperative Wildlife Collection (TCWC 65308). We thank J. T. Collins for providing helpful information and D. Barker, J. A. Campbell and M. E. Retzer for technical assistance.

CNEMIDOPHORUS TIGRIS (Western Whiptail Lizard). **PREDATION.** On 20 June 1987, 1856 h, under a Creosote bush *(Larrea tridentata)* east of Wonder Valley, San Bernardino County, California, at an elevation of ca. 345 m we observed a *C. tigris* holding a subadult side-blotched lizard (*Uta stansburiana*) weighing ca. 2-3 g. The *C. tigris* held the right side of the *Uta* slightly anterior to the hind leg, in its mouth, and was vigorously shaking its head from side to side in an apparent attempt to hit the *Uta* against the rocks and the branches. The *Uta* was curved sharply to the right, and was trying to chew on the right side of the *C. tigris'* neck.

After about three minutes the *C. tigris* disappeared into a burrow under the bush, with the *Uta* still in its mouth. Less than 30 sec later, the *Uta* emerged from the opening, ran toward the nearest bush, and disappeared.

After an additional 10 sec or so, the *C. tigris* also emerged and spent the next seven minutes in what seemed to be searching behavior. It walked around the bush, digging in the leaf litter, and kept going into the multi-opening burrow wherein the *Uta* escaped. The lizard went into the burrow no less than ten times through different openings, spent a few seconds inside, and emerged from another opening. The behavior was different than regular foraging behavior of *C. tigris* in that so much time was spent under the same bush with no pauses for basking. Most importantly, the animal was not observed eating anything during this activity.

At 1907 h we decided to noose the *C. tigris.* The animal vigorously attacked the noose repeatedly. Usually a *C. tigris* which makes an exploratory attack upon a noose will not pursue the issue after a first or second attempt. This animal tried to bite it at least five or six times.

The animal was measured, and found to be an adult non-gravid female, mass = 15 g, SVL = 89 mm and tail base = 65 mm with a regenerated portion of 90 mm. As the animal was part of a marked study population, it was released after measurement.

ELGARIA KINGI (Arizona Alligator Lizard). **ANTIPREDATOR BEHAVIOR.** On 19 June 1987, at 1045 h, in central Arizona ca. 18 km N of Payson along the East Webber Creek a striped whipsnake (*Masticophis taeniatus*) was observed beneath a thicket of grape vines and poison ivy near the base of a 6-10 m tall ponderosa pine tree. The apparent 'sit and wait' foraging mode of the snake (SVL ca. 80-100 cm) and an adult male *E. kingi* (SVL = 108 mm), already in my possession, provided the ingredients to study gerrhonotine antipredator behavior. After setting up my camera gear, the lizard was slowly placed about one meter in front of the snake's head. I touched the lizard's tail and he fled in front of the snake, eliciting an immediate movement to-

Bringing You Herpetology Titles!

SNAKES OF THE ORIENT, A CHECKLIST
by Kenneth R.G. Welch
Orig. Ed. 1987 Price Not Set
ISBN 0-89464-203-0

In this work an attempt is made to list the snake fauna of the Orient as a whole (Pakistan, east of China, south through Asia, to include Japan, Philippine Islands, Indonesia, and Papua New Guinea). The list includes present-day names, original names and references, type locality, distribution and any recent taxonomic references.

HANDBOOK ON THE MAINTENANCE OF REPTILES IN CAPTIVITY
by Kenneth R.G. Welch
Orig. Ed. 1987 162 pp. $17.50
ISBN 0-89874-830-5

The aim of this text is not to tell the reader how to keep reptiles, but to act as a guide, a base for the beginner to start from, and at least in part, a handbook for the more experienced reptile keeper. The text is divided into four parts: an introduction to the maintenance of reptiles in captivity;supplementary notes to the introduction; specific accounts on the keeping of a selection of reptiles in captivity; and a list of species, with references on their maintenance in captivity, breeding results, behavior, and ecology.

BIOMEDICAL AND SURGICAL ASPECTS OF CAPTIVE REPTILE HUSBANDRY
by Fredric L. Frye
Orig. Ed. 1981 468 pp. $62.50
ISBN 0-935078-01-0

In this volume, extensive attention is given to how reptiles can be maintained in a healthy state and how to diagnose and treat sick or injured ones. Included is much new information reflecting recent advances in veterinary medical management of reptiles.

HERPETOLOGY OF AFRICA: A Checklist and Bibliography of the Orders Amphisbaenia, Sauria, and Serpentes
by Kenneth R.G. Welch
Orig. Ed. 1982 304 pp. $23.50
ISBN 0-89874-428-8

HERPETOLOGY OF EUROPE AND SOUTHWEST ASIA: A Checklist and Bibliography of the Orders Amphisbaenia, Sauria and Serpentes
Orig. Ed. 1983 144 pp. $16.00
ISBN 0-89874-533-0

These two texts are guides to the nomenclature and distribution of the amphisbaenids, lizards, and snakes of Africa:, including Madagascar, and adjacent islands and Europe. References are given for the genera as units, and references with present known distribution for the species and subspecies, to include important synonyms. In addition, references are given for families and countries.

SNAKES OF THE WORLD, Volume I: Synopsis of Living and Extinct Genera and Subgenera
by Kenneth L. Williams & Van Wallach
Orig. Ed. 1988 Price Not Set
ISBN 0-89464-215-4

SNAKES OF THE WORLD, Volume II: Synopsis of Living and Extinct Species
by Kenneth L. Williams & Van Wallach
Orig. Ed. 1988 Price Not Set
ISBN 0-89464-216-2

Comprising a cross-indexed, alphabetical list of living and fossil generic and subgeneric snake names, which includes emendations, spelling variations, and errors and providing type species designations for all original descriptions this is an invaluable reference for the amateur and professional zoologist, natural history museums and libraries. A valuable reference source for biologists and others.

wards the fleeing lizard and attempted bite by the snake. Both animals paused, the lizard fled again, and this time the snake successfully bit and held the lizard and a struggle ensued. The snake then responded to my movements by retreating, but it always remained within the thicket. At distances greater than one meter, the snake did not attempt to escape and I could freely photograph the animals.

Figure 1. Striped whipsnake attempting to subdue an Arizona alligator lizard. The lizard is in a "loop" position, biting its tail.

During the first successful bite or ensuing struggle, the snake bit the lizard's neck, the lizard coiled and bit his own tail (ca. 1 cm from the vent) and maintained this 'loop' position (Fig. 1) during the 15 min observation period. Since my presence clearly disturbed the snake and sacrificing my marked lizard would eliminate a lizard from my study population, I terminated the interaction. After releasing the lizard, both animals remained motionless within 50 cm of each other. A few seconds later, the snake tongue-flicked and moved away. The lizard did not move until disturbed again.

This introduction demonstrated two behaviors: 1) striped whipsnakes will attack and attempt to eat Arizona alligator lizards; and 2) *E. kingi* use a 'loop' posture when attacked by a snake. Carpenter (1977. *In.:* C. Gans and D. W. Tinkle (eds.), Biology of the Reptilia, Vol 7, Ecology and Behavior A. pp 335-554. Academic Press, New York) has used literature references to identify the 'loop' posture in four lizard families: Gekkonidae *(Tarentola delalandi);* Cordylidae, *(Cordylus cataphractus* and *C. cordylus);* Varanidae, (*Varanus* sp.); and Anguidae, (*Ophisaurus* sp.). Compton (1933. Copeia 1933:225) also identified this behavior in the anguid *E. multicarinata.*

EUMECES SEPTENTRIONALIS OBTUSIROSTRIS (Southern Prairie Skink). **REPRODUCTION.** Breckenridge (1943. Amer. Midl. Nat. 29:591-606), Clarke (1955. Herpetologica 11:161-164) and Gehlbach and Collette (1959. Herpetologica 15:141-143) provided information on aspects of the reproductive biology of the northern prairie skink (*E. s. septentrionalis*) from Texas. Here I report data on a clutch and hatchlings of this taxon from the state.

On 16 May 1987 an adult female (SVL = 61 mm) was excavated while guarding a clutch of 10 eggs from a shallow burrow under a decomposing pile of *Juniperus ashei* in Hood County, 18.5 km SE Granbury off FM 2174 (Hinton-Parker Ranch). At necropsy, she was found to contain an additional egg in the oviduct which suggests recent clutch deposition. While transferring eggs, two were damaged and the remainder (N=8) were measured (L x W; range 10.1-10.2 x 7.4-8.1, $\overline{X} \pm$ SEM = $10.12 \pm 0.02 \times 7.72 \pm 0.06$ mm) and placed in a small container of damp vermiculite and incubated at room temperature (ca. 23° C). Hatchlings emerged following an incubation period lasting 37-38 days on 21 and 22 June 1987 and measured 24-26 (25.6 ± 1.8) mm SVL. In addition, there was evidence of post-natal molting. Tail coloration was similar to other species of *Eumeces* in being bright violet-blue. The dorsum was uniformly dark brown to black with a light middorsal and two dorsolateral stripes. Head pattern consisted of light lines and orange-red coloration bordering the labial scales. The gular region was light cream and the venter was light grayish brown.

Sabath and Worthington (1959, op. cit.) collected a female skink (SVL = 60 mm) in Harris County that deposited a clutch of nine eggs in late May with average measurements of 11.1 x 6.4 mm. I collected another female *E. s. obtusirostris* (SVL = 69 mm) on 6 June 1987 from the same locale reported herein which did not contain eggs and evidently had previously deposited a clutch.

In conclusion, depending upon geographic locality, *E. septentrionalis* may deposit clutches from mid-May through mid-July with number of eggs/clutch varying from six (usually 10) to rarely as high as 18 (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1-247). Incubation period is variable with temperature and can last from 37 to 52 ($\overline{X}$ = 44.3) days in captivity (Breckenridge 1943, op. cit.; McAllister, this report).

Voucher specimens are deposited in the Arkansas State University Museum of Zoology (ASUMZ 8181-adult, 8182-8189-hatchlings).

I thank C. Russell, E. W. Lewis, W. Parker and J. Hinton for allowing me to collect on their properties and the Texas Parks and Wildlife Department for Scientific Collecting Permit SP044-1.

SERPENTES

DRYMOBIUS MARGARITIFERUS (Speckled Racer). **REPRODUCTION.** This species is distributed from the United States to South America (Peters and Orejas-Miranda 1970. Catalogue of Neotropical Squamata. Part I: Snakes. Bull. U.S. Natl. Mus. 297:(1)397). It is one of the most abundant snakes in Costa Rica, and is usually found in regions below 1200 m.

Two clutches of eggs from two *D. margaritiferus* were collected by the authors at San José Province, Dulce Nombre de Coronado (Female No. 1) and San José Province, Salitrales de Puriscal (Female No. 2). Female No. 1 was taken on 27 March 1983 and female No. 2 on 10 February 1985. The specimens had TLs of 639 mm and 738 mm and SVLs of 447.3 mm and 516.6 mm, respectively. Both have been deposited in the collection of the Instituto Clodomiro Picado, Universidad de Costa Rica and have museum numbers MICP-772 and MICP-773.

The snakes were kept in plastic boxes and provided with water. A clutch of 5 nonadherent eggs from Female No. 1 was found on 29 March 1983 and a clutch of 4 nonadherent eggs from female No. 2 was found on 19 February 1985. Measurements and masses of the two clutches are shown in Table 1. Eggs were incubated on moist cotton in a 500 ml beaker. Ambient humidity was 70%. Incubation temperatures for clutch No. 1 ranged from 23.5-28.0° C daytime to 19.0-22.5° C nighttime. Incubation temperatures for clutch No. 2 ranged from 22.0° C daytime to 20.5-24.0° C nighttime.

Clutch No. 1 hatching began on 31 May 1983 and ended on 2 June 1983 for an incubation period of 64-66 days. Clutch No. 2 hatched on 28 April 1985 after incubating 68 days. Neonate sex ratio for clutch No. 1 was 4.1. Sex ratio for clutch No. 2 was 2.2. Lengths and masses for all neonates are listed in Table 1. All neonates had similar diffuse color pat-

Neonate TL (mm)	258.8 ± 1.7 (230-273)	248 ± 2.4 (225-275)
Neonate masses (g)	4.98 ± 0.3 (4.5-5.4)	4.85 ± 0.4 (4.3-5.1)

* Results are presented as mean $\pm$ 1 S.D.; range.

terns characterized by irregular yellow bands on a dark background in the anterior dorsal region and a vertebral line and bands, posteriorly. There was no evidence of sexual dichromatism.

Fitch (1970. Reproductive cycles of lizards and snakes. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1-247.) noted gravid females in April, July and August whereas we have observed them in February-May. The largest clutch observed by us was 8. We have also observed neonates in March-July and September. These data indicate that reproductive activity in this species may be aseasonal.

We thank José María Gutiérrez for this assistance in the writing of this article.

TYPHLOPS MONENSIS (Mona Island Blind Snake). **PREDATION.** An adult *Typhlops monensis* (ca. 2.4 g; ca. 175 mm SVL) was recovered from the bill of a snowy egret, *Egretta thula,* at Sardinera Beach, an altered portion of southern Mona Island, Puerto Rico. The snake was recovered after I pursued the bird for two minutes; the bird then dropped the specimen to the grass. This beach has more mesic and introduced vegetation than the rest of the island. The bird was discovered on 21 July 1986 at 1544 h at a shady location covered sparsely with grass, elevation ca. 5 m, on a partially cloudy day. The snake showed evidence of being bitten at both ends. The head was crushed, and portions of the body had lacerations probably caused by bites. The specimen has been deposited in the Museum of Biology of the University of Puerto Rico at Rio Piedras, receiving the catalog number UPR-5739.

BOOK REVIEWS

Introduction to the Herpetofauna of Costa Rica/Introduccion a la Herpetofauna de Costa Rica, by Jay M. Savage and Jaime Villa R. 1986. Society for the Study of Amphibians and Reptiles, Contributions to Herpetology, Number 3, viii + 207 pp., 15 figs. color frontispiece, dedicatee photograph; clothbound. $30.00, including shipping charges.

This document is the latest incarnation in a series of preliminary treatments of the herpetofauna of Costa Rica. This, the fourth edition, is the first to be published in both English and Spanish and to be coauthored (the first three editions are in English and authored solely by Jay Savage). The current edition is intended to be another step leading to an eventual full-scale treatment of the Costa Rican herpetofauna by Savage.

The book consists of six major portions, viz.: (1) the introductions to the current editions and the 1980 edition; (2) a distributional checklist; (3) a bibliographic index; (4) the keys for identification; (5) an annotated bibliography; and (6) a scientific name index. These sections are preceded by an attractive photograph of the spectacular anuran *Agalychnis calcarifer* and a dedication of the book to *el sabio* ("the sage"), Rafael Rodriguez C., longtime director of the Department of Biology of the University of Costa Rica.

Some of the book's sections require comment. The distributional checklist utilizes a set of nine geographic areas to compartmentalize the distributions of the Costa Rican amphibians and reptiles. Any arrangement of this nature is bound to have its limitations, as the authors freely acknowledge, but it does serve to compress a mass of distributional data into a small space (15 pp.).

The bibliographic index consists of a series of recent references (since 1950) to the Costa Rican herpetofauna keyed to taxa at various levels and provides "an entry into the extensive literature" on the subject. Systematic papers are emphasized, especially those that will assist with identification.

The keys for identification, which comprise the bulk of this work (155 pp.), are written for taxa at all levels from the class to the species. Happily, the authors avoid the embranglement represented by the subspecies category. The keys are written using features not likely to be affected by injury or preservation. In most cases, where colors are diagnostic and affected by preservation, appearance both in life and in preservative are indicated. Where only color in life is given, other unaffected characteristics are accorded preference. Clear, generally effective illustrations of diagnostic features precede the groups of keys to which they apply.

The annotated bibliography consists of 238 references, including those cited in this work and other key publications. Many of the citations are annotated bilingually, especially when the title is not entirely self-explanatory of content.

This work is a welcome addition to the literature on the Central American herpetofauna for a number of reasons. First, it provides a summarization, preliminary and limited in scope though it may be, of the Costa Rican herpetofauna, as the authors note, "the richest and most diverse in Central America." Savage and Villa list 150 species of amphibians and 212 of reptiles for Costa Rica. The total figure of 362 is up 14 species from that indicated in the first (1973) edition. Summarizations such as this one provide base-line data of interest not only to professional systematic herpetologists but also to wildlife agencies and conservation organizations which are involved in developing programs of management and protection.

The bilingual text signifies the recognition that Spanish is the mother tongue of Costa Rica and that the utility and appeal of the work is considerably heightened by its presentation in two of the three most widespread languages in our hemisphere. I can only hope that the appearance of the current work will help to initiate a trend in bilingual publishing in our field, a trend which will only help to promote cooperative efforts between North- and Latin Americans and underscore our commonality of interest and purpose. The fact that Savage is from the U.S. and Villa from Nicaragua lends further felicity to the project.

An important aspect of such work which remains hidden in the published account is the immense amount of back-breaking and exhausting labor that goes on during the field work that provides the data base for such an effort. Systematic field biology has a much less glamorous reputation than does high-tech laboratory-based research. But those who meet the creatures on their own ground need to be accorded the respect due to people who, in the pursuit of knowledge, will submit themselves for weeks and months on end to the encumbrances and hazards of field work in the tropics. As one of my colleagues who works in a troubled area in Latin America recently told me, "When I'm in the field, I am often running scared."

In attempting to work with some of the keys in this work (especially the generic key to the snakes), I experienced some difficulty and confusion in running through them occasioned by the use of multiple pathways in the key to reach the same taxon. This device (as opposed to keying difficult genera out at different points) necessitates the writing of confusing couplets. For example, with couplet 15 of the snake generic key (single vs. paired prefrontals), both sides will eventually send the user to couplet 63 where once again a decision has to be made about the prefontal condition. It would have been helpful to have notified the user in the introduction to the keys that such a device is utilized or to dispense with it altogether in favor of the more traditional device of keying out the same genus at different points.

To increase the utility and appeal of the work, especially to non-herpetologists, it would have been helpful to include a glossary of technical terminology to supplement the diagrams preceding the keys.

Beyond those minor criticisms, I am pleased to see this effort made to provide information about the Costa Rican herpetofauna to the *costarricenses* and other Spanish-speaking Latin Americans. Attempts such as this one to build bridges of understanding between our two cultures represent a vital step as we struggle to salvage something of the incomparable diversity of life in the American tropics.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1987

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

SSAR GRANTS-IN-HERPETOLOGY-1988

The Society for the Study of Amphibians and Reptiles announces that proposals are now being accepted for the 1988 Grants-in-Herpetology Program. This program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. In keeping with the Society's goal of encouraging the participation of the broadest possible community of people in herpetological research, preference may be given to students, recent graduates, and others who might not have access to other funding sources. All applicants must be members of the SSAR except those applying for Regional Herpetological Society Programs, who must be members of the sponsoring regional society. Applicants are limited to the submission of one proposal in only one category per year. Normally one award is made in each category. This year, however, one award will be given in *either* the Regional Herpetological Society category *or* the Zoo Research category. Further, if proposals in categories 2, 3 and 4 are not judged to be of sufficiently high quality by the GIH Committee, the funds for those categories will be used to create additional awards for Graduate Student Research.

Grant proposals will be considered in the following categories.

1. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

2.HERPETOLOGICALLY ORIENTED CONSERVATION. Proposals should address research on species endangered or threatened at the state, national, or international levels, or address research on potentially threatened habitats or species. Proposals may be received from individual members only and must be accompanied by a letter of support from another member of the SSAR.

3. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society and must be accompanied by a letter of support from the current president of the appropriate regional society. Membership in SSAR Is not necessary for applicants in this category.

4. HERPETOLOGICAL RESEARCH IN ZOOS. Proposals may address any herpetological research endeavor which is conducted at a zoo or that has evident importance to zoo programs. A letter from the director or herpetological curator of the sponsoring zoo must accompany the proposal.

Each proposal must include the following elements: A) ABSTRACT; B) BACKGROUND AND OBJECTIVES of the proposed project, in terms of its relevance to herpetology; C) METHODS of carrying out the research or conducting the project; D) ITEMIZED BUDGET for the project, which should not exceed $430. Travel funds may be included in the budget; E) CURRICULUM VITAE for the applicant or project coordinator (if Regional Society application); and F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding cover page, abstract, bibliography, budget, and curriculum vitae.

Applicants must designate to which one of the four categories their proposal is being submitted. All proposals must be submitted in duplicate and postmarked no later than 31 JANUARY 1988. Failure to meet the deadline or to follow the guidelines may result in elimination of the proposal from consideration. The awards will be announced by 15 March 1988. Submit proposals to:

Thomas H. Fritts, Chair
SSAR Grants-in-Herpetology Committee
U.S. Fish and Wildlife Service
Department of Biology
University of New Mexico
Albuquerque, New Mexico 87131, USA

Successful applicants will be expected to submit to the SSAR a written report of their research or project results within a reasonable time after the project year is completed. They are also encouraged to submit the results of their work for publication in the Journal of Herpetology or Herpetological Review.

Financial contributions by SSAR members, institutions, and other interested benefactors can increase the number of awards in this program. Your tax-deductible contribution to this program will be appreciated by the Society and will directly benefit meritorious research. Contact the President of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization which will match donations made to nonprofit educational organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program. ●

GIH RECIPIENTS, 1987

The Society for the Study of Amphibians and Reptiles is pleased to announce the recipients of Grants-In-Herpetology awards for 1987. Due to budgetary constraints, awards were limited to the category of Graduate Student Research.

John W. Beck, Jr., Department of Biology, University of Miami, Coral Gables, Florida, "An Investigation of the Apparent Competitive Exclusion or Reduction of the Native Green Anole *Anolis carolinensis* by the Introduced Brown Anole *Anolis sagrei* in Nonwetlands Habitats in Southern Florida.

Diana K. Hews, Department of Zoology, Austin, Texas. "Experimental Analysis of Resource Defense, Sexual Selection and the Potential Evolution of Phenotypic Traits in a Territorial Lizard." ●

JOINT MEETING OF HERPETOLOGICAL AND ICHTHYOLOGICAL SOCIETIES JUNE 24-28, 1988

The Society for the Study of Amphibians and Reptiles, The Herpetologists' League, The Early Life History Section of The American Fisheries Society, and The Elasmobranch Society, will meet with the American Society of Ichthyologists and Herpetologists on the occasion of the 75th anniversary of the founding of Copeia, the journal of the ASIH. The joint meetings, including diverse paper sessions and symposia, will be held 24-28 June 1988, on the campus of the University of Michigan. Address inquiries to G.R. Smith, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109, USA ●

FIRST WORLD CONGRESS OF HERPETOLOGY

Canterbury, United Kingdom • 11-19 September 1989

THE CONGRESS will be held at University of Kent and in Canterbury. H.R.H. Prince Philip, President of the World Wildlife Fund, will serve as Patron of our Congress and Professor Angus d'A. Bellairs as Honorary President. The Congress will also serve as the official 1989 meetings of Societas Europaea Herpetologica, Herpetologists' League, and Society for the Study of Amphibians and Reptiles. It will be co-hosted by the Zoological Society of London, Fauna and Flora Preservation Society, Societas Europaea Herpetologica, and The British Herpetological Society.

The Scientific Program, subject to modification, is listed below. Plenary speakers and Convenors are now being invited. *Persons who wish to participate in events should contact the Convenors,* whose names and addresses may be obtained from the Secretariat (see below). There will be poster sessions open to all persons but no oral contributed papers. All presentations will be in English, but discussions can be in other languages.

EXCURSIONS: Pre- and post-Congress trips are planned to Europe, Russia, the Mediterranean, Belize, Honduras, the Amazon, Ecuador, various sites in Africa, Indian Ocean, Pakistan, Malaysia, China and Australia, each led by professional herpetologists. Day or half-day trips to Darwin's home, London, Cambridge, Oxford and Paris are also planned.

FIRST CIRCULAR: The complete program and full details of excursions, including prices, are given in the First Circular, available from the Secretariat. This includes a Provisional Registration Form. Registration begins January 1988; £90 fee covers abstract book and program, refreshments, and costs of hiring meeting rooms and equipment. *Advance registration is strongly encouraged* for planning purposes and to insure that you receive all other announcements promptly.

SECRETARIAT: Address all inquiries to: First World Congress of Herpetology, Ecology Research Group, Rutherford College, University of Kent, Canterbury, Kent CT2 7NY, UK. *Telephone: (0227) 764000, ext. 3501. Telex: 965449.*

NEWSNOTES

HERPETOLOGISTS' LEAGUE ARCHIVES

The Herpetologists' League established an archives with the Smithsonian Institution Archives Program in 1986. We are soliciting correspondence, committee notes, copies of programs, membership files, photographs, and other materials of interest and value to the HL. We would appreciate the donation of any of these materials from members who have participated in HL activities and corresponded with HL officers. We are particularly lacking materials from the early years. Inquiries can be sent to Joseph C. Mitchell, Secretary, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA. Materials can be sent directly to Roy W. McDiarmid, U.S. Fish and Wildlife Service, National Museum of Natural History, Washington, D.C. 20560, USA. Your cooperation with this important HL project is crucial to its success. ●

"TURTLES OF COSTA RICA" PROPOSED

A Spanish/English monograph entitled *The Turtles of Costa Rica* is being prepared. It will review the literature on Costa Rican turtles as well as provide recent and previously unpublished data. The book is intended for professional herpetologists and wildlife biologists as well as for non-professionals with an interest in turtles of the region. We are soliciting notes, photographs or any other material which relate to turtles in Costa Rica; all contributions will be acknowledged in the book. Please contact: Julián Monge-Nájera, Biología, Universidad de Costa Rica, Central America. ●

NIXON GRIFFIS FUND FOR ZOOLOGICAL RESEARCH AWARDS SEVEN GRANTS

The Nixon Griffis Fund for Zoological Research (NGFZR), established in 1984 by New York Zoological Society Trustee Nixon Griffis, awarded seven research grants in June 1987. One of these grants was given in the area of herpetology. The recipients were Adam Asquith and Howard Snell, Ph.D., University of New Mexico, for their study of "Ontogenetic Changes in Nutrients Procurement and Assimilation in the Galapagos Giant Tortoise, *Geochelone elephantopus.*"

Nixon Griffis Fund for Zoological Research grants are available to members of the zoo and aquarium community. Fund recipients may be keepers, curators, veterinarians, or research and consulting biologists. Grants, not to exceed $3000, are awarded semi-annually. Closing periods are January 1st and July 1st. For information about the Fund and grant application procedures, contact John Behler, Coordinator, Nixon Griffis Fund for Zoological Research, c/o New York Zoological Society, Bronx Zoo, Bronx, New York 10460, USA. ●

POISON DART FROG SOCIETY

An effort is underway to establish a formal "society" for those individuals with an interest in poison dart frogs of the genera *Dendrobates, Phyllobates, and Colostethus.* It is hoped that the new society will be international in scope. All members of the herpetological community, both professional and amateur, who share a common interest in these frogs are encouraged to respond to this announcement by writing to the steering committee for more information.

At this point in time there are no funds to support this work. Each respondent is asked to include with his/her initial letter three 22¢ U.S. postage stamps for the mailing of the information packet (those outside the U.S. are requested to include $1.32). Responses should be sent to Dale Bertram, M.D., Chairperson-Steering Committee, Poison Dart Frog Society, One Virginia Terrace, Madison, Wisconsin 53705, USA ●

UPDATED DISTRIBUTION MAPS FOR MINNESOTA AMPHIBIANS AND REPTILES

The 1985 distribution maps have been updated to include all new records as of April 1987. Maps are available from the Minnesota Herpetological Society, Bell Museum of Natural History, 10 Church Street, S.E., Minneapolis, Minnesota 55455, USA. Cost is $4.50 including postage. Those with 1985 maps can send a stamped self-addressed envelope for a listing of new records. ●

PARASITIC NEMATODE SYNOPSIS

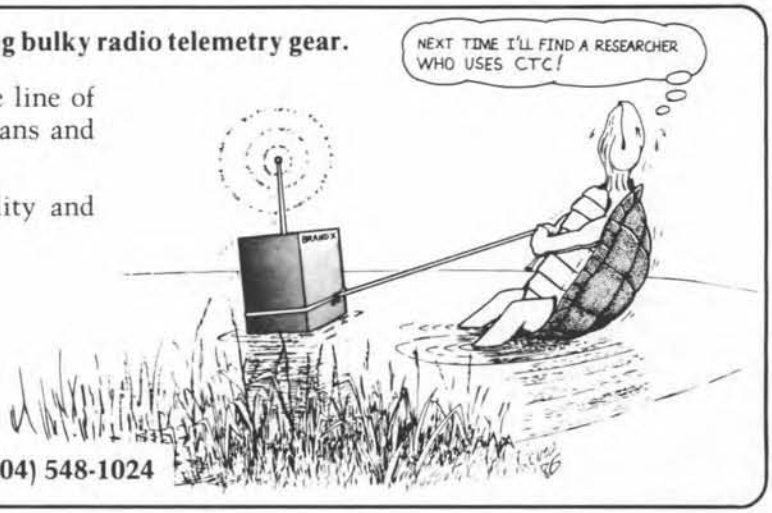
Memorial University of Newfoundland has published Synopsis of the Nematoda Parasitic in Amphibians and Reptiles, by M.R. Baker, 1987. This 325 page publication is listed as Occasional Papers in Biology, No. 11, and is available for $8.00 Canadian from: Occasional Papers in Biology, Department of Biology, Memorial University of Newfoundland, St. John's Newfoundland, Canada A1B 3X9. ●

GRANTS FOR WILDLIFE REHABILITATION

The National Wildlife Rehabilitators Association announces a small-grants program and the establishment of two awards. Two $1000 grants are available for research projects in the field of wildlife rehabilitation or for several smaller research projects each totalling less than $1000. Applicants must demonstrate financial need and submit a typewritten proposal that includes name(s) and resume of personnel involved, objectives of the project, a brief description of how the project will be carried out, a brief statement of the literature reviewed and an itemized budget. An annual report on progress is required.

The awards include the Lifetime Achievement Award given to an individual whose primary identification is with rehabilitation of wildlife and who has contributed to this field in a major way for many years. The Signifi-

No species of study should be burdened with carrying bulky radio telemetry gear.



Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

Custom design, high quality components, reliability and reasonable prices...that's *CTC.*

Please inquire for more detailed information.

Custom Telemetry & Consulting, Inc.

185 Longview Drive □ Athens, Georgia 30605 □ (404) 548-1024

cant Achievement Award is for a person who has contributed something of merit to the field in the last two years. The contribution may be a research finding, publication, organization of a program, or other activity with a major theme in wildlife rehabilitation. Both awards consist of a plaque, $100, and free registration at the NWRA conference where the award will be presented. The deadline for submission of proposals for the research grants or nominations for the awards is 15 December of each year. Proposals should be sent to: Daniel R. Ludwig, Ph.D., Awards and Grants Committee, Willowbrook Wildlife Haven, Willowbrook Forest Preserve, P.O. Box 2339, Glen Ellyn, Illinois 60138, USA. (312) 790-4900 Ext. 283 ●

GRADUATE AND POST-GRADUATE RESEARCH GRANTS

The Edmund Niles Huyck Preserve and Biological Research Station announces the 1988-89 competition for research grants (max = $3,500) for biological research for investigations that utilize the resources of the Preserve. The 2000 acre Preserve is located on the Helderberg Plateau, in the towns of Rensselaerville and Berne, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10- and 100-acre lakes and a 150-ft waterfall. Facilities include a wet and dry lab, small library, and six houses/cabins for researchers.

Deadline for proposals is 1 February 1988. Application material may be obtained from Dr. Richard L. Wyman, Director and Resident Biologist, E. N. Huyck Preserve and Biological Research Station, P.O. Box 188, Rensselaerville, New York 12147, USA ●

BRAILLE FACILITY FOR THE BLIND AT POONA SNAKE PARK, INDIA

Poona Snake Park has, for the first time in this country, introduced Braille Script for the Blind, thus enabling blind persons to learn about snakes. This facility was inaugurated on 26th January 1987, the Republic Day of India. It consists of information charts about each species, prepared in Braille Script. No entrance fee is being charged for the blind and disabled. The blind will also be allowed to touch and feel non-poisonous snakes. Additional information about snakes is recorded on audio cassettes and may be played.

Mr. Neelimkumar Khaire, Director of Poona Snake Park, has also been preparing detailed information, which will be transfered into Braille books. These books will be presented to schools and institutions for the blind.

Anil Khaire
Assistant Director
Katraj, Poona-Satara Road

IN MEMORIAM

PHILIP W. SMITH

On October 11, 1986 as the colors of autumn began to spread over the hills and prairies he knew so well, Philip Wayne Smith died of cancer at Urbana, Illinois. He was born December 2, 1921 near Neoga, Illinois and grew up in a series of small southern Illinois towns where he developed an interest in natural history that was to last all his life. In May 1942, he married Dorothy M. Dearnbarger who was to be his lifelong companion and source of strength and inspiration. Their daughter, April, was born in 1943 and now lives with her husband and two children in Madison, Wisconsin. Also surviving are Philip's mother, Pauline Stewart, two brothers and a sister.

Phil Smith obtained his undergraduate education at Eastern Illinois University from 1940-42 and 1946-47. The interruption coincided with a 37-month period of service in the U.S. Army. He did graduate work at the University of Illinois under the guidance of Hobart M. Smith and received his doctorate in 1953. His association with the Illinois Natural History Survey began while he was still an undergraduate and continued until his retirement in 1979. For more than ten years, he was head of the Section of Faunistic Surveys and Insect Identification. He had a joint appointment as Professor of Zoology in the University of Illinois Graduate School for 14 years. In 1986 he was awarded an honorary D. Sc. degree by Eastern Illinois University.

Phil's contributions to herpetology include his authoritative and popular *Amphibians and Reptiles of Illinois*, his analysis of post-Wisconsin distribution patterns of terrestrial vertebrates in the Midwest, descriptions of the Illinois chorus frog and Illinois mud turtle, systematics of *Pseudacris triseriata* (with Dorothy as co-author), and numerous other papers. However, his contributions to ichthyology were fully as significant and culminated with his monumental and beautifully illustrated *Fishes of Illinois*. He was active in numerous scientific societies serving on the Board of Directors of The Society for the Study of Amphibians and Reptiles and on the Board of Governors of the American Society of Ichthyologists and Herpetologists. He was Editor-in-Chief of *Copeia* from 1959 to 1961.

Phil was a superb field naturalist. Although most of his publications dealt with the midwestern fauna, he was equally at home in the southwestern deserts and austroriparian swamplands. He had an uncanny ability to scan an area and predict what amphibians and reptiles were living there and usually just where they were to be found. This made him a formidable collector, but one who always showed great respect for animal populations and habitats. As a taxonomist, he tended to be conservative, but his insights were almost always sound. His ability as a teacher is reflected in such fine students as Mike Morris and D. S. Liem. Great personal and professional integrity went hand-in-hand with an open, friendly manner and well-developed, sometimes ribald, sense of humor.

After Phil's retirement, he and Dorothy made trips to Africa and Australia where Phil particularly enjoyed observing mammals, a group that really interested him more than cold-blooded vertebrates. The Smiths also had time for other interests including collecting antique dolls, a field where Phil said taxonomic judgment also helped, and amassing a store of Bing Crosby memorabilia. Phil faced his final illness with characteristic courage and grace. During this time he completed his autobiographical book, *A Naturalist in the Environmental Crisis*, and continued to referee manuscripts and review grant requests. At one of our last meetings, I was returning from one of the national herpetology meetings and remarked to Phil that there were a lot of people who remembered him and his work. He replied, "They damn well better!"

They will, Philip, they will.

DICK HILLENIUS

On 4 May 1987, quite unexpectedly, Dr. D. Hillenius died at age 60. Our Institute lost one of its most remarkable members. As a scientific worker and curator of the Department of Herpetology, Dr. Hillenius made important contributions to our knowledge of natural history and was a specialist on African chameleons. The Netherlands will remember him also as a beloved popular writer and poet. Our Institute will not forget his charming personality.

MEETINGS

FIRST CALL FOR PAPERS

"The Management of Amphibians, Reptiles, and Small Mammals in North America" is the subject of a symposium to be held 18-22 July 1988, in Flagstaff, Arizona. The symposium is being co-sponsored by Northern Arizona University (School of Forestry), the USDA Forest Service (Region 3 and the Rocky Mountain Forest and Range Experiment Station), and the Wildlife Society. The intent of the symposium is to bring together scientists and managers to exchange knowledge and ideas on habitat requirements, management needs, and other information on these often overlooked components of North American fauna. Another purpose will be to summarize the state-of-the-science of habitats and habitat requirements of species within these groups. Of particular interest are papers emphasizing habitat models, habitat requirements, sampling techniques and problems, community dynamics, and management recommendations. Single-page abstracts, due two weeks after receipt of this issue of HR, are solicited that emphasize one or more of the above topics. Authors will be notified of acceptance in November 1987. First draft manuscripts will be due 15 February 1988, and will be subjected to a review process and returned to the author. Final drafts will be due 15 June 1988. Proceedings will be published by the USDA Forest Service. For instructions on abstracts and other information, contact Robert C. Szaro or Kieth E. Severson, Rocky Mountain Forest and Range Experiment Station, Arizona State University, Tempe, Arizona 85287, USA (602) 261-4365 or (FTS) 261-4365. For local arrangements contact David R. Patton, NAU School of Forestry, P.O. Box 4098, Flagstaff, Arizona 86011, USA (602) 523-7528. ●

CALL FOR PAPERS

The 1987 Annual Meeting of the Gopher Tortoise Council will be held November 13-14 at Auburn University, Alabama. Council members and interested persons are invited to submit titles and abstracts of papers to be presented. The deadline for receipt of titles and abstracts is 1 October 1987.

For those persons unfamiliar with GTC meetings, they generally consist of a Friday evening social, presentations, state reports, and a panel discussion on Saturday, and an optional field trip on Sunday.

Please submit titles and abstracts to Ed Wester, Co-Chairman GTC, General Biology, 101 Cary Hall, Auburn University, Alabama 36849, USA ●

CONFERENCE ANNOUNCEMENT

The California Energy Commission and the California State College at Bakersfield are co-sponsoring "Endangered and Sensitive Species of the San Joaquin Valley: A Conference on Their Biology, Management and Conservation." The conference will be held 10 and 11 December 1987 at California State College, Bakersfield. Papers will address problems relating to both plants and animals. For further information, registration materials, or paper guidelines, contact Daniel F. Williams, Department of Biological Sciences, California State University, Stanislaus, Turlock, California 95380, USA ●

FEATURES

NOTES ON A LARGE *Melanosuchus niger* SKULL FROM BOLIVIA

The maximum lengths of the larger crocodilians have always been a topic of great interest and conjecture among herpetologists. Many literature accounts refer to large measured specimens or skulls of *Crocodylus porosus*, generally recognized to be the largest of the living crocodilians (Barbour 1924; Greer 1974; Montague 1983). Nevertheless, other than for *C. porosus*, little has been reported on the maximum lengths of other crocodilians. As preserved material of larger specimens is quite rare, discussions have often been centered on anecdotal accounts. Such is the case with the black caiman, *Melanosuchus niger*, a large alligatorid found principally in the Amazon River drainage of South America.

The maximum length of *Melanosuchus* has remained problematical for quite some time. However, it has generally been acknowledged that *Melanosuchus* is the largest of the South American alligatorids. Neill (1971) stated that the largest specimen he had seen was approximately 13 ft (3.96 m) long and that there was no reason to assume that *Melanosuchus* exceeded the length of the American alligator, considered by Neill to be 18 ft. (5.48 m). Guggisberg (1972) noted that in exceptional cases *Melanosuchus* could reach "4.5 m, and even 6 meters." Brazaitis (1973) in his review on the identification of crocodilians stated that males may reach 5 m in length. Medem (1981, 1983) in his definitive work on South American crocodilians considered the maximum length of *Melanosuchus* to be more than 6 meters. This is apparently based on a reported 6.4 m individual killed in Limoncocha, Ecuador in 1957. Unfortunately, no material was saved from this specimen. Medem (1983) also reported that La Condamine (1778) considered the maximum size of *Melanosuchus* to be 20 ft (6.09 m).

In 1981 a large *Melanosuchus* skull was seized by the U.S. Fish and Wildlife Service in Miami, Florida (Seizure tag No. 81-059A, 4 June 1981). The owner reported that he had obtained the skull from a Bolivian hunter in Trinidad, Departamento del Beni, Bolivia. The animal was reported to have been killed within five or six miles of the town, in the Rio Mamore drainage, within the year prior to its seizure in Miami. Upon confiscation, the skull was deposited in the collection of the Florida State Museum, Gainesville (UF 53600). Skull dimensions are presented in Table 1.

Based on data for skull lengths and total lengths of eight *Melanosuchus* reported in Medem (1963), the ratio of total length to skull length (TL/SL) varies from 7.62 to 8.51. The largest specimen in Medem's sample (TL 3.45 m) had a mutilated tail, and based on the average snout-vent/total length ratio (0.48) of the other *Melanosuchus*, this animal should have measured 3.96 m TL. Although the total length and skull length increase with age, the rates of increase vary among specimens and in this small sample there is no consistent ontogenetic increase or decrease in the TL/SL ratio. Nevertheless, the mean TL/SL ratio for the two largest individuals (TL 3.32 m, 3.96 m) was 8.23. Based on this value, and the skull length of the UF Bolivian specimen (58.8 cm), the estimated total length of this *Melanosuchus* was 4.84 m.

As it is reasonable to assume that this skull does not fully represent the maximum attainable size of *Melanosuchus*, it is not unlikely that lengths of over 5 meters are possible for this species. It then appears that the maximum lengths of *Melanosuchus* and *Alligator mississippiensis* are very similar and represent the largest of the living Alligatoridae.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

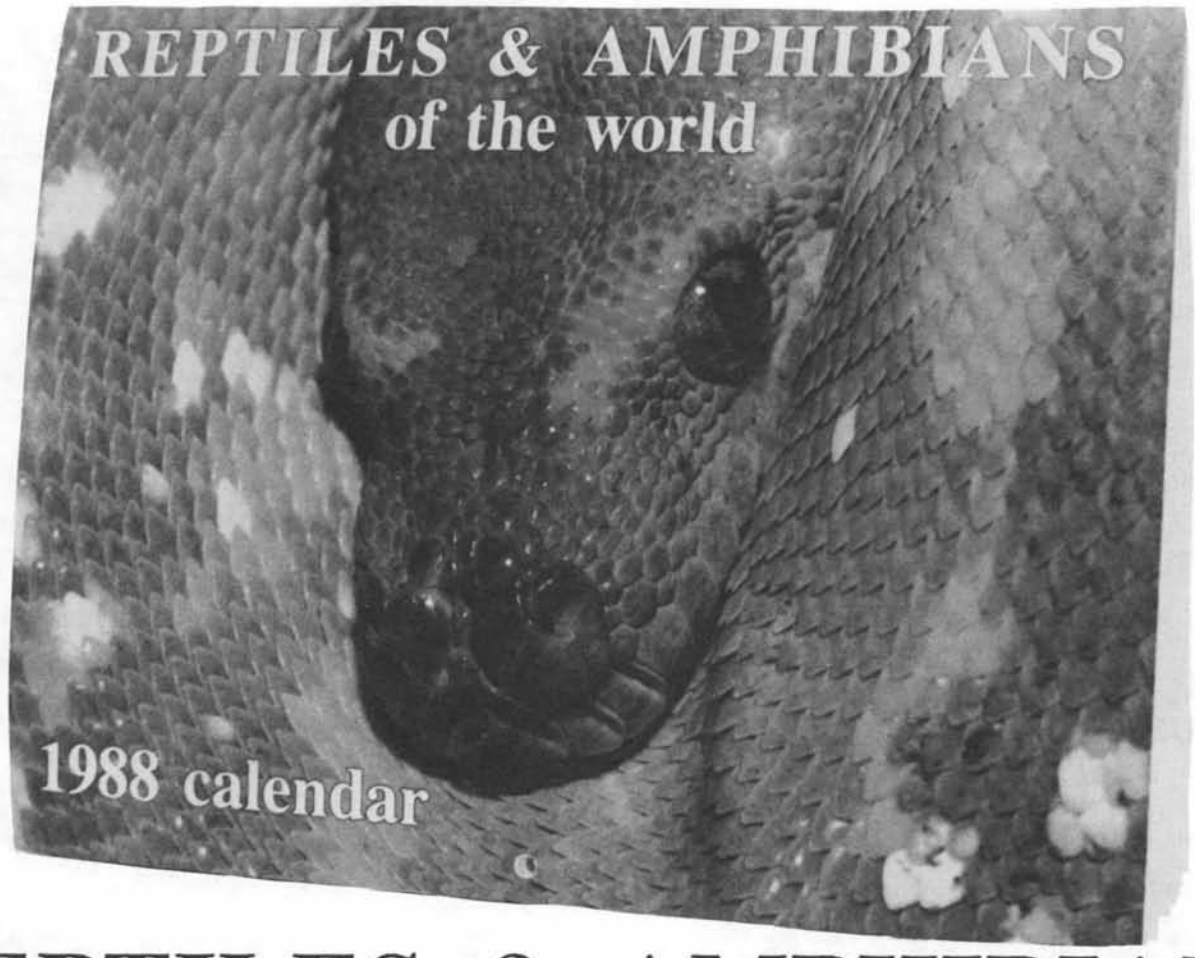
- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $58.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent



Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges. $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

NOTES ON THE NATURAL HISTORY OF THE UNUSUAL CUBAN LIZARD, *Anolis lucius*

The ecology of *Anolis lucius* is unusual in many respects. The species is one of the most vocal in the genus (Ruibal 1964), lays eggs communally (Hardy 1957) and occupies regions of low light intensity such as the mouths of caves and large complicated tree trunks (Ruibal 1961, 1964), perhaps its most unique feature. These habitat associations represent a structural niche specialization that is not found in anoles outside of Cuba (Williams 1969) but is shared by two other Cuban species, *A. bartschi* and *A. argenteolus* (Ruibal 1964).

No work on *A. lucius* has been published since the early 1960s and these studies did not include quantitative data on the unique structural niche. A recent cooperative venture between the Smithsonian Institution and the Cuban Academy of Sciences has allowed North American herpetologists to visit Cuba and work with Cuban colleagues. In the summer of 1983, an opportunity arose to gather data on some aspects of the ecology of *A. lucius*.

MATERIALS AND METHODS

A. lucius occurs from central La Habana province east to western Oriente. The species was reported erroneously by Ruibal (1964) to extend into the province of Pinar del Rio (personal observation). The present study was conducted in the province of Cienfuegos at the Soledad Botanical Gardens. The gardens are composed of plantings of exotic and native trees and bamboos separated by mowed grassy areas. A heavily wooded ridge of limestone rock occupies one part of the garden and is not maintained. The field work was concentrated on the rocky limestone ridge and in an area of large introduced figs (*Ficus* spp.)

Three days were spent at the gardens (29 June to 1 July), and data were collected from 0800 to 1700 h. Habitat variables were recorded using a procedure similar to the censusing method developed by Rand (1964). The study areas were systematically searched, without backtracking; sex, perch type, perch height, perch diameter and insolation (shade, filtered sun, full sun) were recorded for each new lizard. Sex determination at a distance was based on external features (see results) and proved to be accurate, as only two of 57 animals were sexed incorrectly prior to capture. Sexing at a distance was simplified as no hatchlings or subadults were seen or captured. Five perch types were established: ground, rock, small bush ($\leq$ 2 m high), large bush ($>$ 2 m), small tree ($\leq$ 5 m high), and large tree ($>$ 5 m). Perch height was estimated to the nearest 50 cm and perch diameter to the nearest centimeter. No perch diameters were estimated for individuals on rocks. Study areas were censused once or twice each day.

A sample of lizards was captured by hand and by noosing. Cloacal and air temperatures were recorded with a Schultheis thermometer to the nearest degree immediately after capture. Air temperatures were taken at a

Table 1. Mass and length comparison of adult male and female *Anolis lucius*

"A good source of general information and marvelous stories about reptiles and amphibians."—*Herpetologica*

Their Blood Runs Cold

Adventures with Reptiles and Amphibians

Whit Gibbons

Herpetologic lore, lively anecdotal humor, and conservation ethics are combined to provide entertaining, informative reading that conveys the challenge and excitement of scientific inquiry.

Paperback, $9.95t

The University of Alabama Press
P.O. Box 2877
Tuscaloosa, AL 35487-2877

height of approximately one and one-half meters in the shade as near the site of capture as possible. Animals were sexed after capture to confirm the prior visual sexing. Weights to the nearest 0.5 g (Pesola 5 and 10 g spring scales) and snout-vent lengths to the nearest millimeter were taken in the field, after which the animals were immediately released at or near their capture sites.

RESULTS

Females differ from males in being smaller in length and mass, having no dewlap, and in the occasional presence of three or four faint reddish middorsal blotches. The length & mass dimorphism is significant with ranges for males and females barely overlapping (Table 1).

Anolis lucius in the gardens was found exclusively on the rocky ridge and its associated vegetation and on an adjacent group of irregularly spaced large figs with complicated trunks. The ridge and the adjacent figs provided a somewhat continuous habitat. The canopy of the closest fig overlapped the edge of the ridge, and in some cases the canopy of adjoining figs touched. The maximum distance betwen the crowns of any two figs was approximately 50 m. Groundcover between and under the trees was mostly grass and leaf litter. Other parts of the garden were searched for *A. lucius*, including areas with large complex figs, but no *A. lucius* were found. The nearest unoccupied fig that appeared suitable habitat for *A. lucius* was over 200 m from the occupied habitat, and much of this distance was open meadow.

The perch types noted were almost exclusively large trees (figs with complicated trunks) and rocks (164 observations), with only 17 other perch types recorded. Two animals were seen on the ground within 10 cm of a fig, and the remainder were on the vegetation of the rocky ridge. In this area, 13 animals were observed on large trees with simple trunks and two on large bushes.

The fig and limestone rock perch sites were characterized by an abundance of vertical surfaces. Both habitats offered numerous crevices and hollows that the animals used for shelter. The few animals recorded on simple trunked trees had only to move a very short distance to be back on the complicated vertical rock surfaces.

Perch heights for *A. lucius* ranged from 0 to 15 m, with only two lizards out of 195 on the ground. Males perched significantly higher ($t=3.66$; $p<0.001$) than females (Table 2). Perch diameters ranged widely (.01-8.0 m) due to the nature of the figs with large main trunks and many small adventitious trunks. Mean perch diameters were similar for males and females (Table 2).

Animals were infrequently seen in direct sunlight (3% of observations) and most were in filtered sun (35%) or in full shade (62%) (Table 3). Females appeared to occupy filtered sun (40%) more commonly than males (28%); however, the frequencies were not significantly different ($X=2.71$; $p<0.10$).

Mean cloacal temperature for 58 recordings was 29.97 ± 1.71 and there was no significant difference in temperature between the sexes (male 29.64 ± 1.71; female 30.3 ± 1.71). Air temperatures were nearly identical to cloacal temperatures with a mean of 30.03 ± 1.57. The calculated slope of the linear regression of body temperature on air temperature was 0.89 with a y-intercept of 3.36. These data qualify this lizard as a thermoconformer (Huey 1982).

The sex ratio for *A. lucius* is strongly biased in favor of females. In 194 observations there were significantly more females (117) than males (77) recorded, ($\chi^2=8.24$; $p<.005$). This difference in numbers of males and females was corroborated by individual tree censuses. In 25 censuses of 10 trees over a three-day period, more males were counted on a tree three times, more females 18 times and the same number of males and females four times. An attempt was made to collect all the animals on one large fig tree over a two day period. When the tree produced no more animals, six adult males and 12 adult females had been collected.

Casual observations of the distribution of animals in the trees indicated that males defended portions of the figs and that females moved rather freely over the trees and did not defend areas against other females. The free movement of females is also implied by the reports of communal egg laying (Hardy 1957). Males were observed to display towards conspecifics, but no displacements or fights were seen.

Although hourly censuses were not taken in a systematic manner, the activity of *A. lucius* appeared to be spaced evenly throughout the day. The average number of animals seen per hour was similar before (19) and after (14) noon. Prior to a thunderstorm and immediately after a heavy rain, individuals were found inactive, secluded in cracks and crevices.

Vocalizations were frequently heard when animals were grasped during capture. The louder squeaks were clearly audible from over 20 m distant. No unmolested animals were heard vocalizing.

DISCUSSION

In spite of its unusual structural niche, *Anolis lucius* is a typical anole in many aspects of its ecology. It is diurnal, arboreal, and sexually dimorphic. Its shade-loving habits and thermoconformity are also shared with other *Anolis* (Gonzalez and Rodriguez 1982; Ruibal and Philibosian 1974; Rand 1967). However, this species has a few unusual aspects to its ecology.

The sex ratio of adult *A. lucius* strongly favors females. Most studies of anoline lizards have confirmed a 50:50 adult sex ratio (Ruibal and Philibosian 1974; Jenssen 1970; Rand 1967). An adult sex ratio in favor of females has been reported in *A. garmani* (Trivers 1976) and *A. valencienni* (Hicks and Trivers 1983). Our minimal observations on the social organization of *A. lucius* indicate that mating may be polygynous, which would be predicted by the biased sex ratio.

The preference of *A. lucius* for large complex tree trunks and rock surfaces reported by Ruibal (1961, 1964) is generally consistent with results in this study.

This paper demonstrates the need for a more detailed examination of social structure and social behavior in this species. Such studies may elucidate how the biased sex ratio is achieved and maintained as well as determine how the unusual structural niche might be implicated in social structure and behavior.

ACKNOWLEDGMENTS

We thank Noel González, Julio Novo, Stanley Rand and Ernest Williams for their assistance with the field work. Fernando González, the Director of the Institute of Zoology of the Cuban Academy of Science deserves our sincere appreciation for his support of this and other collaborative research between Cuban and United States scientists.

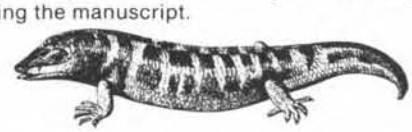
HERPETOLOGICAL HUSBANDRY

See Herp. Review 18(1) for author's instructions.

REPRODUCTION IN CAPTIVE EYELASH VIPERS, *Bothrops schlegeli*

On 19 April 1985, two female *Bothrops schlegeli* were placed with a male in an all glass aquarium (60 X 40 X 32 cm). Female A (5 yrs. old, 640 mm SVL) and female B (10 yrs. old, 673 mm SVL) positioned themselves on various branches in the cage. Although courtship and copulation were not observed, the male was seen coiled on either female during a 26 day period. On 15 May 1985, the male was removed from the cage. Both females were offered adult mice (ca. 30 g) on 16 May, and while female A refused to feed, female B accepted the food item. On 25 June, both females refused to feed.



By August 1985, it was aparent by visual observation that both females were gravid. Mice were offered periodically and were refused. Both snakes were misted with water 3 times a week and drank readily. Photoperiod during gestation was 12D-12L and the temperature during a 24 hour period ranged between 19° C and 35° C under a heat lamp. On 7 January 1986, female A gave birth to 15 live neonates (not measured) without any stillborns or infertile egg masses. One week later, female A accepted food.

The gestation period of this animal was at least 237 days which is 71 days longer than reported by Antonio (1980. Herpetologica 36:231-233). Female A's last prepartum meal was 14 April 1985, giving a volitional anorexia of 268 days which is 137 days longer than reported by Antonio and at least 118 days longer than reported by Blody (1983. Herp. Review 14(2): 45-46).

Female B gave birth on 18 April 1986, to 18 live neonates ($\bar{X}$ = 3.1 g, 169 mm SVL). No stillborns or infertile egg masses were in evidence. The gestation period for female B was at least 338 days. The last prepartum meal was ingested on 16 May 1985. Feeding commenced one week postpartum, a volitional anorexia of 310 days. This is double the periods of gestation and anorexia recorded by Antonio and Blody.

Amphibians and Reptiles of Texas

With Keys, Taxonomic Synopses, Bibliography, and Distribution Maps

James R. Dixon

Texas is situated at the junction of four major physiographic divisions of North America: the Eastern Forests, Great Plains, Rocky Mountains, and Southwestern Deserts. The various environments of the state appear to have their own particular herpetofauna, with some of the state's 283 taxa restricted in distribution according to areas with certain vegetation, soil types, or water sources. With such diverse habitats available, the state has 204 recorded species, from the rare and well-publicized Houston toad *(Bufo houstonensis)* and Atlantic Ridley turtle *(Lepidochelys kempi)* to the garden-variety garter snakes.

The author has prepared an extensive, up-to-date listing of the literature on Texas amphibians and reptiles and a brief history of important herpetological publications, investigators, and authors. More than 150 distribution maps show by county the updated distribution records for Texas herpetofauna, based on 13,000 records selected from the 100,000 total records for the state. A dichotomous key, supplemented by drawings, photographs, and a glossary of terms, and the complete scientific and common names will prove useful to professional as well as amateur herpetologists. 464 pp. 25 photos. 18 line drawings. 156 maps. Bib. Index. $32.50 cloth; $16.50 paper

SNAKES & LIZARDS
Their Care and Breeding in Captivity
John Coborn

An essential guide for anyone wishing to keep fascinating and exotic snakes and lizards

John Coborn draws on a wealth of experience to advise on the sensible selection and care of captive snakes and lizards. The high-quality illustrations, including a large number of excellent colour photographs make this a beautiful as well as informative book, invaluable for both the beginner and the experienced herpetologist.

The most popular and readily available species are described with notes on zoogeography and detailed information about individual requirements. The different kinds of terraria are carefully explained, with instructions for do-it-yourself accommodation. Every aspect of captive husbandry – heating, lighting, feeding, hygiene, veterinary care, lifespans etc – is explained in full.

The final chapter is devoted to captive breeding, particularly important in view of the pressing need to conserve species in the wild. The author describes the recent advances in knowledge and the most modern techniques, which make it possible for any enthusiast to start a breeding programme.

This practical and authoritative handbook will help you to maintain the health and well-being of any captive snakes and lizards – and create an attractive and unusual feature for your home.

The Author

John Coborn has made a lifetime study of zoological subjects – especially herpetology. He has been keeper, then curator, of reptiles and aquarium at a zoological park, and then moved on to be director of a zoological garden. He has organised several national and international herpetological symposia, founded a herpetological society, written many books and articles and made numerous appearances on radio and TV.

NEW HERPETOLOGICAL RECORDS FROM THE SIERRA DE PERIJA, VENEZUELA

In February-March 1985 we conducted a preliminary herpetological expedition to the Serranía de Los Motilones, the southernmost region of the Sierra de Perijá, Distrito Perijá, Estado Zulia, along the Colombian-Venezuelan border. Our samplings yielded a series of specimens which represent new records of occurrence from this mountain range. Specimens are deposited in the Colección de Vertebrados, Universidad de Los Andes, Mérida (CVULA IV). All amphibians were verified by E. La Marca; all reptiles were verified by J. E. García

BUFO GRANULOSUS HUMBOLDTI. 4 km SW El Tukuko, 150 m. 28 February 1985. E. La Marca (CVULA IV-4615).

LEPTODACTYLUS WAGNERI. River at 3 km W El Tukuko. 2 March 1985. E. La Marca (CVULA IV-4616); river at 34 km (by road) SE El Tukuko. 4 March 1985. D. Borjas, J. E. García and E. La Marca (CVULA IV-4616-4625). Northwesternmost localities in Venezuela.

RANA PALMIPES. 5 km SW El Tukuko, on road to Misión San Miguel. 1 March 1985. J. E. García (CVULA IV-4626-4627). Westernmost locality in Venezuela.

AMEIVA AMEIVA PRAESIGNIS. 34 km (by road) SE El Tukuko. 4 March 1985. J.E. García (CVULA IV-4610). Extends range to the Lake Maracaibo Basin (Peters and Donoso-Barros 1970, U.S.N.M. Bull. 297, 1-293).

BASILISCUS BASILISCUS. El Tukuko, 150 m. 4 March 1985 (CVULA IV-4611); 34 km (by road) SE El Tukuko. J. E. García (CVULA IV-4612-4614).

GONATODES ALBOGULARIS ALBOGULARIS. El Tukuko, 150 m. 28 February to 4 March 1985. J. E. García, E. La Marca and P. Soriano (CVULA IV-4593-4607).

LIOPHIS MELANOTUS. El Tukuko, 150 m 1 March 1985. J. E. García and E. La Marca (CVULA IV-4608). Westernmost locality in Venezuela.

LEPTOPHIS AHAETULLA OCCIDENTALIS. El Tukuko, 150 m. 4 March 1985. J. E. García and E. La Marca (CVULA IV-4609). Westernmost locality in the country.

ACKNOWLEDGMENTS

We would like to thank Professor Pascual Soriano, of the Universidad de Los Andes, for provision of working space and for extending many courtesies leading to the completion of our trip to the Serranía de los Motilones.

Contribution No. 2 of the Sierra de Perijá Herpetological Program.

Submitted by **ENRIQUE LA MARCA,** Apartado 116, Mérida 5101, Venezuela and **JUAN ELIAS GARCIA,** Departamento de Biología, Grupo de Ecología Animal, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela ●

BOOK REVIEWS

"VIRGINIA'S AMPHIBIANS AND REPTILES": COMMENTS AND CORRECTIONS

A recent publication (Tobey 1985. Virginia's Amphibians and Reptiles, A Distributional Survey. VA Herpetol. Soc., 114 pp.) provides the most comprehensive available distribution maps for Virginia's amphibians and reptiles. As we noted in a review of this publication (Mitchell and Pague, Herp. Rev., in press), the plotted localities were based on lists of specimens from museum and university collections unverified by the author, the literature, and observations records. Most localities are marked with black dots which represent vouchered and unvouchered records. A few localities which Tobey considered problematic are indicated by hollow dots. We have examined most of the Virginia specimens available in collections, and have had access to the support documentation for Tobey's (op. cit.) maps. In this note we correct some of the maps and focus attention on the periphery of species distributions and questionable records that require verification. Specimens referred to are deposited in the American Museum of Natural History (AMNH), National Museum of Natural History (USNM), and the University of Michigan Museum of Zoology (UMMZ).

Misidentified specimens - The Caroline Co. *Ambystoma jeffersonianum* record is based on an *A. maculatum* (USNM 48920). The *Stereochilus marginatus* locality in Amelia Co. is based on misidentified *Ambystoma opacum* larvae (USNM 196294). The three northernmost *Acris gryllus* records are *A. crepitans* (USNM 198661-2, 243993-6).

Unverified observations - Numerous range-margin localities are based only on observations. These are: *Ambystoma jeffersonianum* - Hanover Co. (Funderburg et al. 1974. Bull. Md. Herpetol. Soc. 10:57-58); *Bufo terrestris* -Surry Co.; *Limnaeodus ocularis* - Mecklenburg Co.; *Agkistrodon piscivorus* - Brunswick Co.; *Clemmys muhlenburgii* - Montgomery Co.; *Crotalus horridus* - Greensville, Halifax and Mecklenburg counties (Byrd 1728. Histories of the dividing line betwixt Virginia and North Carolina, run the year of our Lord 1728, The Westover Manuscripts, reprinted, Petersburg, VA, 1841; Byrd 1733, Journey to the Land of Eden, The Westover Manuscripts, Petersburg, VA, 1841); *Deirochelys reticularia* - central City of Virginia Beach; *Kinosternon subrubrum* - Rockingham Co.; *Opheodrys vernalis* - Bland, southwestern Giles and Washington counties; *Pituophis melanoleucus* - Augusta, Bath and Botetourt counties (Burch. 1940. Va. J. Sci. 1:35-40; Uhler, et al.. 1939. Trans. 4th N. Am. Wildl. Conf., pp 605-622); *Regina septemvittata* - Chesterfield Co. There is no specimen-supported verification of *Anolis carolinensis* in the Great Dismal Swamp National Wildlife Refuge in Virginia.

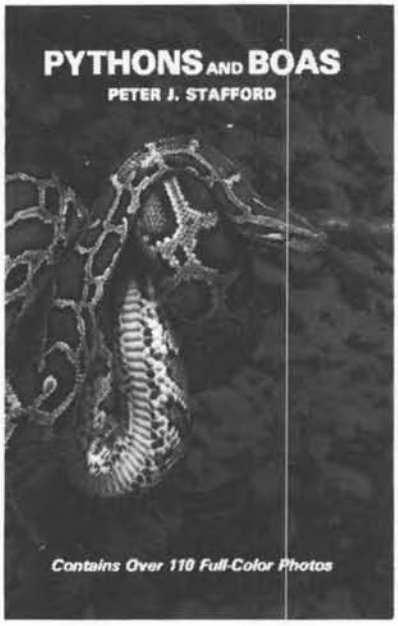
Other questionable records - Several locality records are supposedly based on specimens in museum and university collections, which we cannot find in the respective collections. We assume these records were plotted incorrectly, or were based on specimens which were subsequently reidentified. These records are: "*Ambystoma opacum* - Montgomery Co." (UMMZ): "*Amphiuma means* - Amelia Co." (USNM); "*Necturus maculosus* -Montgomery Co. and Pulaski Co." (USNM, AMNH); "*Pseudacris triseriata* - City of Virginia Beach" (USNM); and "*Rana palustris* - Accomack Co." (USNM). The specimens for the two northernmost *Desmognathus auriculatus* localities in Hanover County cannot be located in the Randolph-Macon College col-

LIVE CRICKETS

. . .an excellent food source for most amphibians and reptiles.

With a dryweight analysis of 60% protein, 35% lipid and 5% carbohydrate, it is obvious why crickets are considered a valuable nutritional food source for amphibians and reptiles.

Fluker's Cricket Farm offers crickets in a variety of sizes and stages, from 1 day (1/8") to 6 weeks old (1") at a cost of $12/thousand (or a minimum order of 500 for $9.00) plus postage. Shipments are made year-round with guaranteed live delivery.



Fluker's Cricket Farm offers fine, healthy specimens. Our company takes pride in personal service, striving for individual attention and efficient shipping. We would appreciate an opportunity to serve you.

Phone (504) 343-7035.

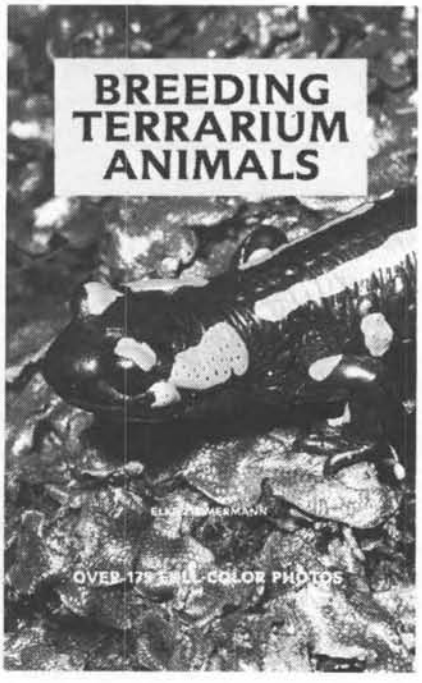
USEFUL NEW HERPETOLOGICAL TITLES FROM T.F.H.



***PYTHONS AND BOAS* • Peter J. Stafford**

Pythons and boas have long been among the most fascinating of snakes, and with continued encroachment upon their habitat they are now also among the most threatened. *Pythons and Boas* provides an up-to-date look at the Boidae, with emphasis being placed on the boids as threatened animals whose futures lie with increased captive breeding by concerned hobbyists. Every genus is covered, from the largest pythons to the smallest wood snakes, with summaries of what is known of their natural history and care in captivity. A special chapter spotlights methods of breeding boas and pythons in captivity. This volume includes the only available modern checklist of the species and subspecies of living boids, as well as a simple key to the genera. Heavily illustrated, with 111 color photos and numerous black and white illustrations and maps.

***BREEDING TERRARIUM ANIMALS* •**
Dr. Elke Zimmermann

Breeding Terrarium Animals provides the much-needed guidance to this often complicated phase of the terrarium hobby. The author presents her experiences and those of her colleagues in condensed but very readable form filled with information of use to hobbyists and professional herpetologists alike. Profusely illustrated in color, the book covers almost 100 species in detail, with basic information on dozens more. For the main species there are discussions of care, identification, and distribution, followed by detailed observations on the breeding behavior, incubation, and care of the young. The other species are grouped with the major species by their similarity in breeding behavior and listed with such essentials as number of eggs, incubation period, and temperature preference. In total, almost 350 species are covered, from axolotls to *Xenopus* among the amphibians and agamas to *Xantusia* among the reptiles. The discussions of the complicated life histories of the fascinating poison arrow frogs (*Dendrobates* and *Phyllobates*) are especially detailed. Good discussions of general terrarium maintenance, rearing food animals, and methods of egg incubation round out the book.

lection and are presumed lost. Our unpublished information suggests they were misidentified *Desmognathus fuscus*.

Toads in Virginia, especially in the southeast, are occasionally difficult to identify (Blem 1979, Cat. Am. Amph. Rept. 223; pers. obs.). The putative *Bufo terrestris* (USNM 198568) from Hanover County appears to be a hybrid between *B. woodhousei fowleri* and *B. terrestris*. However, the locality lies well to the northwest of the range of *B. terrestris*, and we would not expect *B. terrestris* genetic influence in this area. In our opinion, this locality should not be included in the range of *B. terrestris*.

The southernmost locality for *Ambystoma jeffersonianum* is based on a juvenile specimen (USNM 21234), which was given to the University of Maryland in 1966. It could not be located in a recent search (R. D. Worthington and A. Wynn, pers. comm.). The northwestern Brunswick Co. specimen of *Amphiuma means* (USNM 49624) was donated to the Instituto Butantan, Brazil in 1950. These localities need verification.

We thank F. J. Tobey for allowing us access to the documentation used to develop the maps, and the following curators for allowing us to examine the Virginia specimens under their care: C. B. Knisley (Randolph-Macon College), G. R. Zug and R. W. McDiarmid (USNM), R. G. Zweifel (AMNH). A. Kluge (UMMZ) sent us a data printout for Virginia. Our Virginia research is supported by the Nongame Species Program of the Virginia Commission of Game and Inland Fisheries.

The Encyclopedia of Reptiles and Amphibians, edited by Tim Halliday and Kraig Adler. 1986. 160 pp. 160 color photos and illustrations. Facts on File, Inc., 460 Park Avenue South, New York, New York 10016, USA. Hardbound, $24.95.

This relatively concise volume consists of a series of 19 articles, each written by a professional zoologist with expertise and/or research interests in that particular area of herpetology. The name "encyclopedia" implies a collection of information on manifold topics, and this text conforms nicely with this concept. Some general topics covered include the evolution, biology, classification and ecology of amphibians and reptiles.

The format adhered to throughout the book is logical and easily followed. Evolutionary and fossil histories of each class are presented first and are then followed by morphological, anatomical, reproductive, and other characteristics of the class. The ecologies and known distributions of species are collectively used to characterize the families. In addition, much interesting general information on familial members is included. Boxes are used to explain or describe subject matter in greater detail. A current classification of families within an order (e.g. families recognized under the order Squamata, suborder Sauria) is telegraphically presented at the end of each ordinal (or subordinal) section. A small distributional range map and the number of genera and species are included for each family. Following the family descriptions are more lengthy articles elaborating particular topics of interest, such as "Repellent Defenders, antipredator mechanisms in salamanders and newts" and "Frog Chorus, vocal communication in frogs and toads."

Approximately 160 color photographs and drawings are used effectively to illustrate species or to visually explain the text. All are of excellent quality and would be well worth the cost of the book by themselves.

Although mistakes have been kept to a minimum, a few were overlooked. The red salamander *Pseudotriton ruber* has been positioned in two families, the Salamandridae and the Plethodontidae. Nomenclatural misspellings and inconsistencies are also few in number but present (e.g. *Ascaphus truei* and *A. trueii*).

In one instance, word selection or additional explanation might have helped dispel a widely believed misconception that constrictors kill prey by crushing. The caption of a pygmy python killing a mouse states that the mouse is "crushed to death." Although the crushing of prey may sometimes occur, suffocation by constriction is the more common cause of prey death.

This encyclopedia has appeal to amateurs and professionals alike and is a book that all of us interested in amphibians and reptiles should have on our shelves and consult frequently. The information is conveyed visually and verbally in a manner appreciated by most readers. Much of the technical jargon found in other texts and scientific papers has been omitted, so the casual reader as well as the professional can readily grasp the information and concepts presented.

TIMOTHY O. MATSON

Wade Oval, University Circle
Cleveland, Ohio 44106, USA

The Encyclopedia of Reptiles and Amphibians by Tim R. Halliday and Kraig Adler (Editors). 1986. xvi + 144 pp. Facts on File, Inc., 460 Park Avenue South, New York, New York 10016, USA $24.95.

Ho hum! Another popular book on amphibians and reptiles? Another "coffee table" picture book? Not really. This book is something special, for it consists of well-written text and informative panels interwoven among superb, eye-caching illustrations. All of this is encompassed on 144 pages of high-quality paper (21.5 x 28 cm) in a hard cloth cover encased in an attractive dust jacket.

Nineteen distinguished herpetologists contributed sections of this book. The editors of the volume and Graham Bateman, editor of the series, have done an outstanding job of uniformity of treatment and integration of text and illustrations. The plan of the book consists of major articles introducing the two classes and separate major articles dealing with each of the three orders of amphibians and six orders and suborders of reptiles. Each

The Snakes of Australia

An illustrated and descriptive catalogue of all the known species. Gerard Krefft, 1869 Facsimile Edition, 1984

The first detailed study of Australia's fascinating snakes. Only 700 copies of the original work were published. 1000 facsimile edition copies are now offered for sale.
100 pages including 12 hand coloured lithographs faithfully reproduced on fine quality paper.

of these 11 chapters is introduced by a factual panel giving the number of families, genera, and species, distribution (with map), summary of habitat, size, color, reproduction, and longevity. Each of the chapters dealing with the nine orders and suborders concludes with a separate description of each of the families. In those accounts of the salamanders, frogs, turtles, lizards, and snakes, fact-box summaries for each family are appended; these give the numbers of genera and species, distribution (with map), size, color, body form, and lists of species and genera referred to in the text. Ten double-page special features highlight important aspects of the biology of amphibians and reptiles.

The introductory chapter on amphibians (Kraig Adler) discusses the origin of amphibians in the classical rhipidistian-*Ichthyostega* story and provides a brief account of locomotion and a good review of the diversity of reproductive modes. This is followed by three special features (all by Adler) dealing with metamorphosis, adaptive coloration, and parental care.

The chapter on caecilians (Marvalee H. Wake) is an informative, but brief, review that emphasizes feeding, locomotion, and reproduction. The chapter on salamanders (Tim Halliday and Paul Verrell), which displays the European influence by emphasizing newts, is followed by feature articles on salamander courtship (Tim Halliday) and on antipredator mechanisms (Edmund Brodie). A more lengthy chapter on frogs (Anthony Arak) complements information provided in the chapter on amphibians. Two special features deal with frogs—locomotion (George R. Zug) and vocalization (H. Carl Gerhardt).

The introductory chapter on reptiles (Angus d'A Bellairs) includes succinct discussions of the origin, classification, skin, skeleton, and reproduction, followed by special features on dinosaurs (Alan J. Charig) and thermoregulation (Raymond B. Huey). The chapters on the groups of reptiles include turtles (Edward O. Moll), lizards (Arnold G. Kluge and Gordon Schuett), snakes (Herndon G. Dowling), amphisbaenians (Carl Gans), the tuatara (Joan Robb), crocodilians (H. Robert Bustard), and a special feature on venomous snakes and their venoms (Sherman A. Minton).

Within the accounts of the major groups there are special feature boxes on particular subjects. These include (1) finding breeding ponds by salamanders, (2) marine toads *(Bufo marinus)* in Australia, (3) frog toxins and poisons (4) longevity in turtles, (5) the versatile lizard tongue, (6) the expendable tail of lizards, (7) courtship in lizards, (8) unisexual lizards, (9) sense organs in snakes, (10) brooding behavior in snakes, (11) courtship and aggression in snakes, (12) how snakes swallow their prey, and (13) parental care in crocodilians.

Authors of each of the groups have emphasized beneficial aspects of amphibians and reptiles to humans and the decline of many kinds of amphibians and reptiles because of human exploitation and especially habitat destruction. In the fact-box summaries at the end of each account the threatened or endangered status as listed by the IUCN and the listing by CITES are given.

The illustrations are an important aspect of this book. The 113 color photographs (some covering an entire page) are for the most part excellent and in themselves provide a comprehensive view of amphibians and reptiles. Many of these photographs are not just pictures of the animals but of the animals doing something [e.g., *Chiromantis xerampelina* beating a froth nest (p. 9), *Desmognathus fuscus* brooding its eggs (p. 21), *Hyla arborea* leaping (p. 57), *Dendroaspis polylepis* hatching from an egg (p. 66), *Varanus komodoensis* feeding (p. 107), *Crotalus atrox* striking (p. 131), and especially *Crocodilus niloticus* drowning an impala (p. 141)]. The photographs are accompanied by meaningful captions. I noted only two errors in the captions. The photograph of a *Ceratophrys* (p. 37) is incorrectly identified; the individual is *C. cornuta*. The caption for the photograph of a *Liasis perthensis* coiled around a mouse (p. 121) unfortunately states that the mouse is being "crushed to death."

Four illustrators contributed to the book. Some stylized morphological drawings and paintings of dinosaurs are the work of Michael Long, whereas other generalized morphological drawings were done by Simon Driver, and a few black and white sketches were drawn by Denys Ovenden. The great majority of the artwork consists of color paintings by David M. Dennis, who, among other things, illustrated representative taxa of all of the families. Those of us who have seen original paintings by Dennis will be somewhat disappointed by the reproductions in this book, because many of them seem to lack the depth and subtle tones characteristic of his original paintings.

The book concludes with a bibliography of 103 titles and a list of 16 herpetological journals, a glossary of 320 technical terms and an index of more than 2400 entries guiding the reader to subjects, common names, scientific names, and illustrations.

There are some minor errors [e.g., the eggs of all phyllomedusine hylids are enveloped in leaves (p. 49), and centrolenids have minute eyes (p. 49)]. Also, there are some taxonomic errors [e.g., use of the generic name *Hylambates* for *Leptopelis* (p. 51), and the association of arthroleptine ranids as a subfamily of the Hyperoliidae (pp., 51, 55)] and one major inconsistency—3000 species of amphibians (p. vi) versus the more nearly correct number of 4015 (p. 2). One ancient error in the literature has persisted on page 51 in this encyclopedia, in which it is reported that *Hylambates (= Leptopelis) brevirostris* broods eggs in the buccal cavity. This was dispelled 50 years ago by G. K. Noble (see Duellman and Trueb 1986, Biology of Amphibians, p. 44). Some statements are misleading. For example, I take exception to the statement (p. 47) that ghost frogs *(Heleophryne)* are rare; they have restricted distributions. Likewise, the statement (p. 94) that there is no evidence to substantiate the decline of native species of lizards because of the introduction of exotic lizards in southern Florida may be correct in that there are no population studies providing the necessary empirical data. However, to someone like myself who was used to seeing *Anolis carolinensis* on nearly every bush in Miami in the 1950s where now *Anolis sagrei* abounds, there is no doubt that the introduction of *Anolis sagrei* had had a profound effect on the population of *Anolis carolinensis*.

The great amount of information in a very concise form is a tribute to the diligent efforts of the editors working within the constraints established by the publishers. However, the usefulness of the book would have been enhanced by the inclusion of some material and the elaboration of other subjects. For example, the morphological sections generally are weak and give no idea of skeletal diversity. Information on population dynamics, community ecology, and historical biogeography is lacking. Other special features that could have been added are (1) energy metabolism, (2) color change, (3) water economy in amphibians, (4) the tongue and feeding in amphibians, and (5) diversity of amphibian larvae with respect to habitat. Inclusion of these materials and appropriate illustrations would have added perhaps 20 pages to the book.

These minor criticisms aside, the Encyclopedia is an excellent introduction to the fascinating world of amphibians and reptiles. The book has many potential users. Professional herpetologists will want to keep a copy handy for answering those annoying queries: How long do turtles live? How many kinds of frogs are there? What is the longest snake? It is adequate as a text in an introductory undergraduate course in herpetology. I think it is more useful as a text than Goin, Goin and Zug, 1978, Introduction to Herpetology. In combination with the volumes on mammals and birds in the same series, it is an excellent reference for a course in vertebrate natural history. Because it is written in a style that can be understood and appreciated by the layperson, the book belongs in every high school library and on the shelf of every nature enthusiast. For everyone else, it is a fine addition to the coffee table, for the pictures alone are worth the price of the book.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

AUTHORS SOLICITED FOR SALIENTIA ACCOUNTS IN CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

Several species in the anuran fauna of the United States and Canada have had no authors assigned, or the assignments have been relinquished by their prospective authors. If you would care to volunteer to write the Catalogue account for one or more of the species listed below, please contact the undersigned. Accounts available are: *Bufo americanus, B. compactilis, B. debilis, B. punctatus, B. speciosus, Hyla arenicolor, H. chrysoscelis, H. crucifer, H. eximia, H. versicolor, Hypopachus variolosus, Pseudacris clarki, P. triseriata, Rana catesbeiana, R. pipiens, R. utricularia (sphenocephala), Scaphiopus bombifrons, S. hammondii, S. intermontanus, S. multiplicatus, Syrrhopus cystignathoides, S. guttilatus,* and *S. marnockii.*

In addition, the Catalogue is open to accounts of species, genera and higher categories from anywhere in the Americas, and authors are sought for these, too. Contact Richard G. Zweifel, Salientia Editor, Catalogue of American Amphibians and Reptiles, Department of Herpetology, American Museum of Natural History, New York, New York 10024, USA ●

HERPETOLOGY IN MEXICO— A MEXICAN PERSPECTIVE

The Regional Society Liaison Committee, in cooperation with the Zoo Liaison Committee, is proud to sponsor a morning paper session on Monday afternoon, 10 August, at the Joint Annual Meeting of The Society for the Study of Amphibians and Reptiles and The Herpetologists' League, at the Hotel Mocambo, Veracruz, Mexico.

The title of the paper session is "Herpetology in Mèxico - A Mexican Perspective." Five speakers from various Mexican Institutions have been invited to participate. They include: David Lazcano, Jr., Museo de Historia Natural, Universidad Autónoma de Nuevo Leon; Eduardo Fanti Echegoyen, Departamento de Herpetología de la Universidad de Guadalajara; Oscar Flores Villela, Curator of Herpetology, Museo de Zoología, Facultad de Ciéncias, Universidad Nacional Autónoma de Mèxico; Antonio Ramírez Velásquez, Instituto de Historia Natural, Departamento de Zoología, Chiapas Zoo; and José María Reyes, Dirección General de Conservación y Ecología de los Recursos Naturales.

The speakers will be limited to 25 minutes for their presentations and 5 minutes for questions and answers. For more information check in at the registration counter or contact Stephen Hammack, Chairman, Regional Society Liaison Committee or Donal Boyer, Chairman, Zoo Liaison Committee.

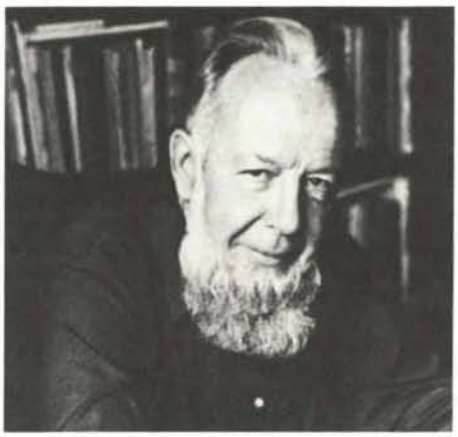
NEWS NOTES

SMITHSONIAN REPRINTS CATALOGUE OF NEOTROPICAL SQUAMATA

The Smithsonian Institution Press has reprinted a widely used checklist of Central and South American snakes and lizards. The Catalogue of the Neotropical Squamata (Part I: Snakes, by James A. Peters and Roberto Donoso-Barros; Part II: Lizards and Amphisbaenians, by James A. Peters and Braulio Orejas-Miranda, reprint with new material by P. E. Vanzolini) includes complete primary synonymies and keys for identification in both English and Spanish. P. E. Vanzolini's update brings all the taxonomic nomenclature current through 1985 and early 1986.

This 148 page paperback is now available at $29.95 ($1.75 postage and handling for the first book, 50¢ additional for each additional book) from: Smithsonian Institution Press, P.O. Box 4866, Hampden Station, Baltimore, Maryland 21211, USA.

For those individuals with the original Catalogue, the Smithsonian Institution has published the "Addenda and Corrigenda to the Catalogue of Neotropical Squamata" as SHIS #70. This may be obtained free of charge from the Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560, USA. Requests should include a self-addressed mailing label. ●



IN MEMORIAM

ANDREI GRIGORYEVICH BANNIKOV (1915-1985)

A. G. Bannikov, noted Soviet zoologist and conservationist and senior author of the best known field guide to the herpetofauna of the USSR, died of cancer in Moscow on 17 October 1985. At the time he held the Chair of Zoology at the Moscow Veterinary Academy and was vice-president of the All-Union Herpetological Committee. Although most of his 400 papers and 30 books dealt with mammals and birds, he made many important contributions to herpetology. He published detailed monographs on the ecology of the commonest species of Russian amphibians and reptiles, wrote the first significant review of the herpetofauna of Mongolia, and led the popularization of herpetology in his native land.

Professor Bannikov's major herpetological works include "Contributions to the Biology of Amphibians" (1956, with Denisova), "Amphibians and Reptiles of the USSR" (1971, with Darevsky and Rustamov), "Animal Life: Amphibians and Reptiles" (first edition 1971; second edition 1985, with Darevsky, Denisova, Drosdov and Iordansky), "Field Guide to Amphibians and Reptiles of USSR" (1977, with Darevsky, Ischenko, Rustamov and Scherbak), and "Problems of Conservation and Natural Uses of Reptiles" (1978, with Flint and Makeev).

In addition to his zoological work Bannikov was very active in conservation. He began the Red Data Book project in the USSR and organized several nature reserves in the Soviet Union. He was elected a vice president

Andrei Grigoryevich Bannikov

of the International Union for the Conservation of Nature, which in 1973 awarded him its Golden Ark prize for his conservation activities. The previous year the World Wildlife Fund presented him its Gold Medal, for conservation of the saiga antelope.

Fuller obituaries are published in: Wildlife and Wildlife Management (Moscow), issue 2, 1986, pp. 16-17; Ecology (Sverdlovsk), issue 2, 1986, pp. 95-96.

ZDENEK VOGEL

"It is with regret and sadness that we announce the passing of Professor Zdenek Vogel, Zoologist and Author, at age 73, on December 9, 1986." Announcement by the Zdenek Vogel Family (Prague, Czechoslovakia)

Professor Vogel is perhaps best known from the publication of his book, *Reptile Life*, which included species of reptiles that occur in countries of Eastern Europe and USSR. At the time of its publication, the early 1950s, communication between the socialist countries and the West was virtually non-existent. This book, then, was particularly popular among herpetologists in the United States wanting to know more about herpetology in the socialist countries.

Professor Vogel had travelled to various socialist and non-socialist countries (including Cuba, Venezuela, and others) as a consultant and to pursue his herpetological interests, publishing materials intended primarily for the interested generalist. Many of his works appeared in Czech and/or German and eventually English. ●

SOCIETIES

CONFERENCE ON CALIFORNIA HERPETOLOGY

A Conference on California Herpetology will be held on 10-11 October 1987, sponsored by the regional herpetological societies of California, and hosted by the Los Angeles County Museum of Natural History.

Seventeen distinguished herpetologists and three roundtable discussions will explore aspects of California's reptiles and amphibians of interest to professional and amateur herpetologists as well as conservationists and naturalists in general. The latest research on endangered and rare species, the most recent techniques of captive propagation, and other topics will be discussed.

For further information call (818) 982-8520, (213) 744-3371, or (619) 672-1096, or write: C.H.C./S.W.H.S., P.O. Box 7469, Van Nuys, California 91409, USA

Conference fee is $30 ($25 before Sept. 25).

FORMATION OF A HERPETOLOGICAL ORGANIZATION IN MEXICO

In August 1985, during the VIII National Congress of Zoology in Saltillo, Coahuila, approximately 30 individuals interested in herpetology met and formed the "Comité Herpetológico Nacional" (CHN). The CHN is composed of three members of the Mexican herpetological community: M.S. Zeferino Uribe-Peña (President), Biol. Rubén Castro-Franco (Secretary), and M.S. Oscar Flores-Villela (Board Member). Addresses are given below.

The original goals of the CHN were (1) to produce a preliminary directory of Mexicans interested in the study of amphibians and reptiles, and (2) within a period of one year to organize a meeting with three main objectives: to identify the main lines of current research by Mexican herpetologists; to identify all Mexicans involved in herpetological research and their professional addresses; and to discuss the feasibility of establishing a formal herpetological society in Mexico.

The preliminary directory contains names and addresses of about 50 professionals and students (copies can be obtained from Rubén Castro-Franco). The "Primera Reunion Herpetológica Nacional" was held at the Universidad Autónoma del Estado de Morelos (UAEM), Curenavaca, Mexico, 3-5 September 1986. Eighty four persons attended. Of the 77 persons polled, 22 were professionals, among them curators, full-time researchers and technicians, 24 were undergraduate students, 13 students doing theses on herpetology, and eight graduate students. The participants belonged to seven major institutions (five universities and two institutes from Mexico) as well as one university in the United States.

- Universidad Nacional Autónoma de México
  Instituto de Biología, Estación de Biología Tropical "Los Tuxtlas", Facultad de Ciencias, Facultad de Medicina, and Escuela Nacional de Estudios Profesionales Iztacala
- Universidad Michoacana de San Nicolás de Hidalgo
  Escuela de Biología
- Universidad Veracruzana
  Facultad de Ciencias Biológicas
- Universidad Autónoma de Nuevo León
- Universidad Autónoma del Estado de Morelos
  Escuela de Ciencias Biológicas
- Instituto Nacional de Investigaciones Sobre los Recursos Bióticos
  Programa Fauna de México
- Instituto de Ecología A.C.
- Oklahoma State University
  Department of Zoology

Forty papers were presented: 14 of them were completed research projects and the remaining papers were the results of current ongoing investigations. The research covered community ecology, biogeography and faunal studies, reproduction, and taxonomy.

On the whole, the reunion was a success. Throughout the present year the CHN will focus its activities mainly on preparation for the organization of a formal society, send representatives from the Mexican herpetological community to international events (such as the World Congress of Herpetology), and meet jointly with SSAR and HL in Veracruz, Mexico, in August 1987. Also, the CHN plans to search for funds to publish a small newsletter, to promote the organization

HERPETOLOGICAL COLLECTING AND COLLECTIONS MANAGEMENT
by
John E. Simmons
1987 Herpetological Circular No. 16

This handbook is essential for anyone who collects and preserves reptiles and amphibians. It outlines techniques for collecting and preparing specimens, and details cataloging, management, and maintenance procedures that are essential to both small and large collections. Includes a comprehensive 350-entry bibliography. This circular is an excellent personnel training guide, and is a necessity for individuals, universities, and zoos who maintain or work with preserved collections.

Pre-publication price $4.50 postpaid ($6.00 after 30 September 1987)

SOPTOM

The Station d'Observation et de Protection des Tortues des Maures (SOPTOM) was founded in 1985 by French and English conservationists concerned about the decline of *Testudo hermanni* and other reptile species in the Massif des Maures. The initiative has received strong support and interest from local people and the Municipal Council of Les Mayons. International support has come from the Conservation Committee of the Societas Europaea Herpetologica, the Flora and Fauna Preservation Society and the Tortoise Specialist Group of the IUCN. The conservation programme draws on the results of research carried out by the Ecology Research Group of the University of Kent and by Dr. Marc Cheylan of the University of Montpellier.

The activities of SOPTOM include conservation (habitat restoration, egg protection, and protected rearing of juveniles, as they relate to Hermann's tortoise), park and reserve protection, observation and study, publicity and public relations, and educational productions for use in schools.

Further information may be obtained from: Bernard Devaux, SOPTOM, La Tuilière des Anges, 83340 Les Mayons, France. ●

MEETINGS

ASZ AND FIVE OTHER SOCIETIES TO MEET IN NEW ORLEANS, LA., 27-30 DECEMBER 1987

The 1987 Annual Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, International Association of Astacology, and the Society of Systematic Zoology will be held at the Hyatt Regency Hotel in New Orleans, Louisiana, during the traditional post-Christmas period.

The Call for Contributed Papers has been issued by ASZ, and an *August 10* deadline for receipt of abstracts of papers (oral or poster presentations) has been set.

Symposia presently scheduled are: (1) Adaptive Sex Ratios and Sex Ratio Theories, (2) Kin Recognition in Animals: Empirical Evidence and Conceptual Issues, (3) Comparative Aspects of Aging of Neuroendocrine Systems, (4) Biology of the Crocodilia, (5) Phylogeny of Immune Defense Mechanisms in Parasitic Infections, (6) Behavioral Neuromodulators: Cellular, Comparative and Evolutionary Patterns, (7) The Developmental Neurobiology of the Frog: A Symposium in Honor of Jerry J. Kollros, (8) Constraints of Bioenergetics on Animal Population Dynamics, (9) Crustacean Egg Production, (10) Adaptive Coloration in Invertebrates, (11) Aquatic Locomotion, (12) Vicariance Biogeography: Theory, Methods and Applications, (13) Is the Organism Necessary?, and (14) Science As A Way of Knowing — Form and Function.

Meeting plans include several socials, special programs, commercial exhibits and a Job Placement Service. Hotel rates are $55 for single and $60 for double rooms at the Hyatt Regency Hotel. Housing and Registration deadlines are November 20. Forms will be available mid-September.

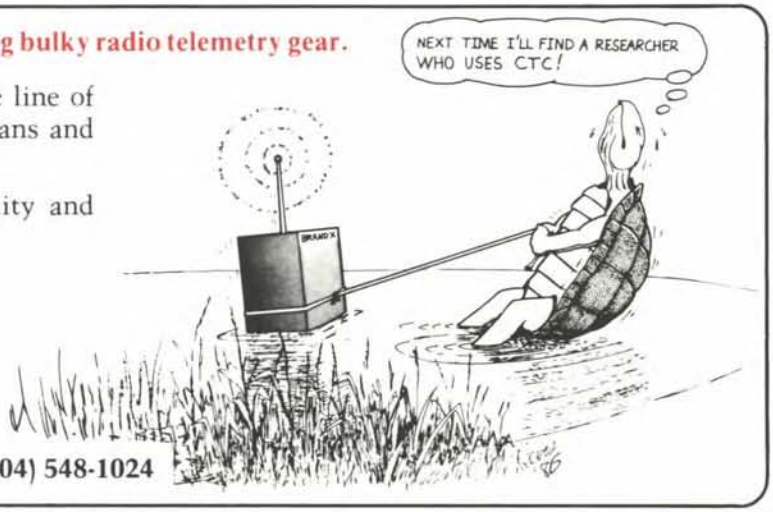
This meeting is hosted by Tulane University, with Milton Fingerman, Claudia deGruy and Merle Mizell co-chairing the Local Arrangements Committee. For more information contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, Box 2739 California Lutheran University, Thousand Oaks, California 91360 (telephone (805) 492-3585). ●

SINO-JAPANESE HERPETOLOGICAL SYMPOSIUM HELD AT GUANGZHOU, CHINA

The first Sino-Japanese Herpetological Symposium, proposed by the Chinese Society of Herpetologists and co-sponsored by the Herpetological Society of Japan, was held from 25 August to 5 September 1985 at South China Normal University in Guangzhou (formerly Canton), China. Seventy-three herpetologists from four countries attended this meeting, the first international herpetological meeting ever held in China. We were very sorry that Dr. Hajime Fukada, who as president of HSJ was actively involved in the planning, could not attend due to illness. Fifteen participants came from Japan, seven from the United States, one from Switzerland, and 50 were Chinese herpetologists. Pan Jionghua, R. Goris, Ding Han-po, K. Adler, J. Garzoni, M. Matsui and Zhao Ermi were selected as members of the platform party for the Opening Ceremonies.

Seventy-one papers and abstracts covering a wide range of topics (13 on systematics, 11 on faunistics, 3 on morphology and ultrastructure, 10 on ecology, 8 on physiology, 4 on developmental biology, 4 on reproductive biology, 5 on karyology, 2 on parasitology, 2 on snake-bite, 6 on toxicology, and 1 each on behavior, biochemistry, and paleontology), were presented at the symposium. Papers and abstracts were published in *Acta Herpetologica Sinica* (volume 4, pages 55-73, 133-376, 1985 and volume 5, pages 1-66, 1986). Copies of these issues can be obtained on an exchange basis by writing to me. Most of the

No species of study should be burdened with carrying bulky radio telemetry gear.



Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

papers were read and discussed at the sessions. Following is a list of the papers presented.

Session 1: Masafumi Matsui, chair.
Y. Sawai, Japan Snake Institute, Japan: Snakebites in the Asian area.
R. Goris, Yokohama City University, Japan: Infrared reception in snakes.
M. Kuramoto, Fukuoka University of Education, Japan: Anuran amphibians of the Ryukyu Islands and Taiwan.
T. Seto, Shimane University, Japan: Karyological studies of Hynobiidae (Caudata).

Session 2: Zhao Ermi, chair.
K. Adler, Cornell University, USA: The orientation of desert lizards.
R. Conant, University of New Mexico, USA. Zoogeography and phylogeny of the North American members of the genus *Agkistrodon.*
K. Kardong, Washington State University, USA: The rattlesnake strike—offensive and defensive behavior.
Pan J., South China Normal University, PRC: Advances in herpetological research in China.

Session 3: Ding Han-po, chair.
Pan J., South China Normal University, PRC: Amphibian fauna of the Guangdong mainland.
Fang R., Shaanxi Normal University, PRC: A new *Scutiger* from Shaanxi.
M. Toyama, Okinawa Prefectural Office of Education, Japan: Herpetofauna of Okinawa Islands.
Liu M., Liaoning University, PRC: Herpetofauna of Liaoning Province.
Yuan H., Ministry of Forestry, Xinjiang, PRC: Reptiles of Shaanxi Province.
Li D., Tsunyi Medical College, PRC: Reptiles of the karst region of Libo, Guizhou.
Zheng J., Fujian Normal University, PRC: Sea turtles along Fujian coastal region.
Zhou Y., Shenyang Normal College, PRC: Sea snakes of Liaoning Province.

Session 4: Y. Sawai, chair.
Qi Z., Shanghai Institute of Biochemistry, Academia Sinica, PRC: Human thrombin and thrombin-like enzyme from Pallas' pit-viper venom.
Wang Q., Fujian Medical College, PRC: Thrombin-like enzyme from hundred-pace pit-viper.
Zeng G., Jiangxi College of Traditional Chinese Medicine, PRC: Cobra venom and its neurotoxic components.
Sun J., Sun Yat-sen Medical University, PRC: Cardiotoxicity of cobra cardiotoxin in the rat.
Chen Y., Shanghai Institute of Biochemistry, Academia Sinica, PRC: Taxonomic significance of snake venom phospholipase A_2.
Jiang J., Dung Feng Hospital, Changzhou, PRC: Three severe symptoms caused by snake-bite.
Hong S. and Liu K. Fujian Medical College, PRC: Detoxification of crotaline venom by DTPA.
Hao W., China Medical University, PRC: Snake venom applications.

Session 5: Pan Jionghua, chair.
Liu C., South China Normal University, PRC: Distributional grouping districts of herptiles in China.
Song M., Shaanxi Institute of Zoology, PRC: A new gecko from Shaanxi Province.
M. Matsui, Kyoto University, Japan: Variation and systematics of Chinese toads.
Hu Q., Chengdu Institute of Biology, PRC: Hengduan Mountains and amphibian evolution.
T. Hikida, Kyoto University, Japan: Geographic variation of *Eumeces elegans.*
Zong Y., Shanghai Museum of Natural History, PRC: Studies on Chinese *Chinemys.*
Tian W., Chengdu Institute of Biology, PRC: Description of a new subfamily of anurans.

Session 6: Kenneth Kardong, chair.
Gao J., Fujian Normal University, PRC: Karyotypes of two species of *Microhyla.*
Wu G., Chengdu Institute of Biology, PRC: Karyotypes of *Amolops* frogs of the Hengduan Mountains.
Chen J., Nanjing Normal College, PRC: Karyotypes of three species of *Gekko.*
Yang Y., Zhejiang Medical University, PRC: Karyotypes of four colubrid snakes.
Qu Y., Zhejiang Medical University, PRC: Studies on snake blood.
Huang M., Zhejiang Medical University, PRC: Ultrastructure of snake retinas.
Zhang J., South China Normal University, PRC: Amphibian trematodes.

Session 7: C Yoshida, chair.
Wang P., East China Normal University, PRC: Heat metabolism and thermoregulation of *Elaphe.*
S. Mitsui, Kushikino Laboratory, Yomeishu Seizo Co., Japan: Food habits of mamushi in the field.
Liu L., Fujian Medical College, PRC: Fujian sea snakes and their food habits.
A. Moriya, Kushikino Laboratory, Yomeishu Seizo Co., Japan: Growth and food consumption of mamushi in captivity.
Gu H., Hangzhou Normal College, PRC: Population variation of mamushi bred on an islet.
K. Isogawa, Kushikino Laboratory, Yomeishu Seizo Co., Japan: Reproductive frequency of mamushi in nature.
Huang J., Qimen Snake-Bite Institute, Anhui, PRC: The biology of young hundred-pace pit-viper.

Session 8: Zhao Kentang, chair.
M. Toriba, Japan Snake Institute, Japan: Some problems in taxonomy of mamushi.
Kou Z., Yunnan University, PRC: *Amphiesma venningi,* a record new to China.
Jiang Y., Chengdu Institute of Biology, PRC: Studies on Chinese *Japalura* species.
H. Ota, Kyoto University, Japan: Variation of *Japalura* in Ryukyu and Taiwan.
Yao C., Northwest Normal University, PRC: Circulatory and urogenital systems of *Eryx miliaris.*
Feng X., Lanzhou Medical College, PRC: Skeletal system of *Hyla tsinlingensis.*
Wang P. and Zhou Kaiya, Nanjing Normal College, PRC: Studies on diving bradycardia of *Trionyx sinensis.*
Zhao E. and Zhang F., Chengdu Institute of Biology, PRC: Comparisons of the skeletons of four hynobiid genera.

Session 9: Kraig Adler, chair.
T. Kusano, Tokyo Metropolitan University, Japan: Population dynamics of *Hynobius nebulosus tokyoensis.*
Wen Y., Guangxi Medical College, PRC: On habits of *Ichthyophis glutinosus.*
Zou S., Xüzhou Normal College, PRC: Some changes during hibernation of *Bufo gargarizans.*
Wang P., East China Normal University, PRC: Seasonal changes in blood sugar of *Bufo gargarizans.*
Su B., South China Normal University, PRC: On food habits of 31 frog species of Guangdong.
Zhang J., Fujian Normal University, PRC: Reproductive frequency of *Rana limnocharis.*

Chen B., Anhui Normal University, PRC: Relationships between activities and metabolic rate of Chinese alligator.

Huang C., Academia Sinica, Beijing, PRC: Nesting and hatching behavior of the Chinese alligator.

The scientific sessions went on for four days. Two additional days were arranged for local tours to the Dinghu Mountain Forest Reserve and to Sevenstar Crags, a karst region in Zhaoqing, and for a downtown tour and a visit to the biological department of South China Normal University. During the evenings there were banquets and technical videotape and motion picture presentations as well as a cruise on the Pearl River.

Following these activities on the mainland, from 1 to 5 September most persons participated in a five-day trip to Hainan Island, a survey tour to observe the fauna and flora of this tropical isle. After arrival by jet plane in the capital city of Haikou, participants travelled by two large buses along the west coast to the southernmost tip of the island, and then along the east coast back to Haikou, thus encircling the entire island. They visited the South China Institute of Tropical Crops near Nadoa, the Bawangning Mountains and the "Border of the Earth," an historic site west of San-ya. During the stay at the Bawangning Forest Station in the central mountains, participants were divided into four smaller field parties specialized by individual interest. They made the best use of the one day and two nights there in searching for turtles, lizards, and snakes as well as frogs. The following 15 species of amphibians and 25 species of reptiles were caught and observed on the island: Frogs: *Bufo melanostictus, Hyla simplex, Rana guentheri, R. limnocharis, R. livida, R. macrodactyla, Amolops ricketti, Ooeidozyga laevis, Buergeria oxycephalus, Chirixalus doriae, Polypedates leucomystax, P. mutus, Microhyla ornata, M. pulchra, Kaloula pulchra:* Turtles: *Platysternon megacephalum, Cuora hainanensis, Trionyx steindachneri;* Lizards: *Calotes versicolor, Leiolepis belliana reevesii, Hemidactylus bowringii, H. frenatus, H. garnotii, Gehyra mutilata, Eublepharis lichtenfelderi, Takydromus sexlineatus meridionalis, Eumeces chinensis, Lygosoma (Sphenomorphus)* sp., *Mabuya longicaudata, M. multifasciata, Scincella reevesii;* Snakes: *Ramphotyphlops braminus, Amphiesma stolata, Dendrelaphis p. pictus, Oligodon formosanus, Ptyas korros, Xenochrophis piscator, Enhydris plumbea, Naja naja atra* and *Trimeresurus s. stejnegeri*. A more narrative account of the Hainan excursion has been published by Adler (Bull. British Herpetol. Soc., 16:17-19, 1986).

On 1 September Drs. K. Adler and R. Goris were invited to present lectures, as representatives of our group, at Hainan University, Haikou. On the same evening Professor Lin Ying, a prominent plant ecologist and president of Hainan University, entertained all the participants with a large banquet at the Banquet Hall of Qiong Yuan (Hainan Garden Hotel). Later, the group was stranded on Hainan by a typhoon and could not leave the island until 7 September, so an impromptu extension of the meeting was convened at the hotel until we could return to Guangzhou.

The next meeting of the Chinese Society of Herpetologists will be held at Fuzhou, Fujian Province, in 1988.

FEATURES

OVIPARITY IN *Leiolopisma jigurru* AND A BRIEF REVIEW OF REPRODUCTIVE MODE IN *Leiolopisma*

In describing *Leiolopisma jigurru*, Covacevich (1984) noted that "no data on breeding biology for this new species is available because only a handful of specimens are known." The species is known only from the summit of Mt Bartle Frere in tropical north Queensland, and is separated from other *Leiolopisma* species in temperate Australia by over 1500 km.

On preparing one of the paratypes of *L. jigurru* (Queensland Museum J39493, SVL = 62mm, collected 7-8 November, 1981) for clearing and alcian/alizarin staining, it was found to be a gravid female, containing 4 thickshelled oviducal eggs, two in each oviduct. Measurements of the four eggs are: 11.3 x 6.0 mm, 11.3 x 6.3 mm, 12.4 x 6.0 mm and 12.0 x 5.9 mm. The thickness of the egg-shell indicates that the species is oviparous.

Rawlinson (1974a, 1975) and Greer (1982) divided the Australian *Leiolopisma* into two groups, the *L. baudini* and *L. spenceri* groups. In those characters known for the species (midbody scales 30, colour hues lacking, long limbs, saxicoline habits), *L. jigurru* is a member of the *L. spenceri* group. However, the monophyly of these groups has not been proven. The morphological characters used to define the saxicoline to arboreal *L. spenceri* group in particular are a suite common to a number of rock-dwelling lygosomines of several genera (Covacevich and Ingram 1978, 1980; Ingram and Rawlinson 1981; Covacevich 1984) and have apparently evolved several times in response to a rocky environment.

The evolution of viviparity in cold-climate reptiles, including lygosomines, is a recurrent phenomenon (Blackburn 1982; Shine and Bull 1979; Shine 1985; but see criticisms by Tinkle and Gibbons 1977). As such, oviparity in *L. jigurru* is surprising, as the only known locality is in a cool, montane climate (Covacevich 1984). Retention of developing eggs, leading to live-bearing, is particularly disadvantageous to species which rely on agility to feed and avoid predation (Shine and Bull 1979; Shine 1980). While this may explain retention of oviparity in *L. jigurru*, which inhabits the largely bare surfaces of granite boulder fields (Covacevich 1984), it does not explain why the other species of the *L. spenceri* group, which are also saxicoline or arboreal and inhabit cold climates, are viviparous.

Leiolopisma as currently conceived (Greer 1974; Hardy 1977) is diagnosed largely on primitive characters. The only derived character state defining the genus is the presence of a windowed eyelid, a character that has evolved many times in lygosomines (Greer 1974). Both egg-laying and live-bearing species are known in the genus (*sensu* Hardy 1977; Hardy and Hicks 1980; Arnold 1980). Available data (Table 1) show little evidence of any geographic trends in reproductive mode, although they do tend to follow suggested species groupings. Oviparity has been retained in at least six species complexes within *Leiolopisma (trilineatum-duperreyi-platynotum, zia, jigurru, lichenigerum-suteri, nigrofasciolatum-greeri* and *telfairii)* from geographically distant areas, and the oviparity/viviparity dichotomy, together with the variation present in the genus in other phylogenetically useful characters (e.g., frontoparietals fused/separate, supranasals present/absent, pterygoid teeth present/absent and division of temporal scalation), suggests that further division of *Leiolopisma* may be warranted.

As *L. jigurru* is a rare species in collections (Covacevich 1984, records only 10 specimens) it is worth noting that a second specimen (R106978, N.W. peak of Mt Bartle Frere, 1440m a.s.l., SVL = 45.5 mm) of *L. jigurru* has recently been identified in the Australian Museum collection.

ACKNOWLEDGMENTS

I am grateful to J. Covacevich and A.E. Greer for arranging the specimen loan, and to A. Greer, H.G. Cogger, B.R.H. Farrow, R. Sadlier and R. Shine for comments on the manuscript. J. Robb kindly confirmed her published observations on reproductive mode in New Zealand taxa.

NEW REPRINT
Deadline for Prepublication Prices: 1 September 1987

BIOLOGIA CENTRALI-AMERICANA

Reptilia and Batrachia by Albert Günther

This classic covers the herpetology of Middle America, from the Texas border through Panamá, written by an acknowledged authority. Seven hundred species are covered. The full-page plates are some of the finest likenesses of amphibians and reptiles ever produced.

The reprint will be about 500 pages in length including 76 plates (12 in full color). Bound in cloth in a format measuring 8 1/2 x 11 inches (21.5 x 28 cm). A full description with a sample color plate was published in *Herpetological Review*, March 1987.

CLOTHBOUND BOOK (ISBN 0-916984-17-6):
Prepublication price to SSAR Members $28
Price to Institutions and Non-members and to everyone after 1 September 50
SET OF 12 COLOR PLATES (wrapped in protective wrapper):
Prepublication price to SSAR Members $10
Price to Institutions and Non-members and to everyone after 1 September 18

NOW PUBLISHED!

INTRODUCTION TO THE HERPETOFAUNA OF COSTA RICA

by Jay M. Savage and Jaime Villa R.

A bilingual review, in both English and Spanish, of the 150 amphibian and 212 reptile species inhabiting Costa Rica. There is a checklist that also gives the range for each species; extensive illustrated keys to species and additional keys to tadpoles and coral snakes; annotated bibliography with index; index to published illustrations of tadpoles; and a comprehensive index. 225 pages, clothbound, 8 1/2 x 11 inches. A full description was published in *Herpetological Review*, September 1986.

CLOTHBOUND BOOK (ISBN 0-916984-16-8) $30

ORDERING INFORMATION. Send orders to Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR." Prices include shipping charges (book rate) within USA; all overseas orders will be billed only for the *additional* charges in excess of domestic rates. Publications are sent at customer's risk; however, packages can be insured at customer's cost. Overseas orders must make payment in USA funds, by International Money Order, or by MasterCard or VISA (in which case account number and expiration date must be provided). A complete pricelist of Society publications and information on membership are available on request from Dr. Taylor.

L. alazon	?	

[1]species taxonomy follows Hardy (1977)
[2]grouping suggested by Towns (1974)
[3]as all New Zealand taxa except *L. suteri* have been presumed to be live-bearing (McCann 1955; Sharell 1966; Robb 1974, 1980), the existence of captive-bred *L. infrapunctatum* implies live-bearing in this species
[4]the alpha-taxonomy of the *Leiolopisma* of New Caledonia and Vanuatu is poorly known, and is currently under revision by R. Sadlier of the Australian Museum (pers. comm.). The taxonomy and species groups used here are those tentatively proposed by Zug (1985).

LIFE HISTORY NOTES

See Herp. Review 18(1) for author's instructions.

ANURA

***ATELOPUS SPUMARIUS*. VOCALIZATION.** Calls of only a few species in the genus *Atelopus* have been adequately described. We report on the call of an adult male *Atelopus spumarius* (UMMZ 182554; 19.3 mm SVL) from Loreto Province, Peru. The frog was captured along the bank of a small stream on 24 May 1985, ca. 3 km north of Nauta. The call was recorded at 26° C, on a Uher recorder Model 40001 (19.5 cm/s) and a ECM53FP Sony microphone. Five calls were analyzed on a Kay Electric Sound Spectrograph 7030A with both wide band (300 Hz) and narrow band (45 Hz) filters.

The frog called while clinging to the side of a large plastic jar and was barely audible across a quiet room. The slightly bilobed vocal sac protruded only slightly and pulsated rapidly during each twittering buzz-like call. The pulse rate during the last half of the call was faster than during the first half (Fig. 1A). The frequency increased ca. 300 Hz during the call, although the last pulse was slightly lower than the preceding one (Fig. 1B).

Lescure (1981. Bull. Mus. natn. Hist. nat. Paris. 3:893-910) described the calls of three subspecies of *Atelopus spumarius*, including one from Peru designated as *A. s. spumarius*. Our sonogram is similar to that of Lescure's for *A. s. spumarius* and the other subspecies. There are discrepancies between the measurements of call parameters however. The frequency of the calls we recorded were 200-400 Hz lower, the duration shorter, and the number of pulses only half of those reported by Lescure (Table 1). Although both Lescure's and our recordings were made from one frog each, these large differences suggest that the call of *A. s. spumarius* may vary geographically. Lescure's specimen came from Yubineta, in the Río Napo drainage, whereas our specimen was collected ca. 200 km south, from the Río Marañon drainage.

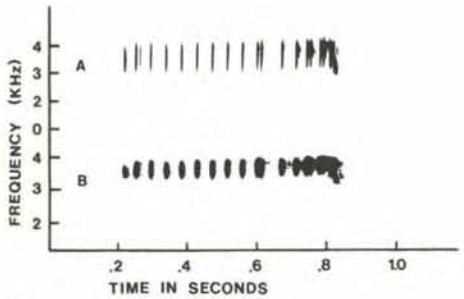

Figure 1. Vocalization of *Atelopus spumarius* analyzed with wide (a) and narrow (b) band filters.

Table 1. Frequency (Hz), duration (msec), pulses/sec, number of pulses and intercall interval (sec) for *Atelopus spumarius*.

Variable	$\bar{X}$ (S.D.)	Range
Frequency		
Beginning	3578 (98)	3450-3690
End	3900 (100)	3770-4050
Duration	680 (30)	670-710
Pulse Rate		
Beginning	23.4 (2.2)	27.5-30.6
End	61.3 (7.9)	52.2-71.4
No. of Pulses	23.4 (2.4)	20-27
Intercall Interval	2.2 (0.3)	5.4-8.0

These patterns are remarkably similar to the buzz call of *A. chiriquiensis* (Jaslow 1979. J. Herpetol. 13:141-145), which is not a member of the *flavescens* group (Lescure 1981. op. cit.). Jaslow (1979. op. cit.) reported that the buzz call was given by the male especially in response to other males and occasionally led to combat. He also gives evidence for similar buzz calls in *A. pulcher* and *A. v. zeteki* and suggests that it also serves to attract females. The frog we recorded began calling spontaneously in isolation; therefore the function of the call is speculative, but certainly was not an agonistic response.

***DENDROPHRYNISCUS MINUTUS*. REPRODUCTION.**
Since 1977 reproduction of *Dendrophryniscus minutus* (Bufonidae) was observed in the area of the biological station at Panguana, Peru (9°37'S, 74°56'W. elev. 260 m Schlüter 1981. Salamandra 17(3/4): 99-105; Schlüter 1984. Ökologische Untersuchungen an einem Stillgewässer im tropischen Regenwald von Peru unter besonderer Berücksichtigung der Amphibien. Diss. Univ. Hamburg. 300 pp.). Chorusing frogs of this species were found at an almost completely shaded blackwater pond from October to March (rainy season). *D. minutus* was active on the forest floor by day, but oviposition occurred mainly at night.

Until now different authors suggested (Duellman and Lynch 1969. Herpetologica 25(4):231-240) or described (Crump 1974. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 61:1-68), that *D. minutus* deposited its eggs in water. In Panguana the reproductive mode of this species is quite different. Using Duellman's outline of 29 reproductive modes in anurans (Duellman 1986. Biology of Amphibians. McGraw Hill, New York), *D. minutus* fits mode No. 18. During amplexus females (X = 20.5 mm SVL) deposit their clutches, which consist of two gelatinous strands of about 250 to 350 mm (photograph in Schlüter 1984. Op. cit.: p. 76) on leaves, twigs, and roots up to 50 cm above water level. Somtimes strands can be found in contact with water. Developmental time to hatching takes six days (air temperature between 24 and 26 °C).

Observations on captive larvae show that larvae adhere to roots etc. at different water depths on the first day after hatching and drop into the water. From the second day onward, they remain horizontal on the bottom, sometimes moving short distances by slow movements.

RANA CATESBEIANA (Bullfrog). **FEEDING.** Although bullfrogs are known to prey upon birds (see summary in Bury and Whelan 1984. U.S. Fish and Wildl. Serv., Res. Publ. 155:1-23), most avian species taken are those which frequent aquatic habitats. Here I report the first record of predation on an adult golden-crowned sparrow *(Zonotrichia atricapilla).*

On 16 October, 1986 at 1016 h, an adult male bullfrog (114 mm SVL) was captured while I was electroshocking for fish on the San Joaquin River at Durham Ferry State Recreation Area, San Joaquin County, California. Upon capture, the frog disgorged a fresh adult golden-crowned sparrow. The bird was apparently ambushed by the frog in the concrete riprap next to the river when it came to get a drink in the foggy, early morning hours. The bullfrog had an injured right eye (opaquely colored) which did not respond, as the left eye did, to the collector's hand movements.

My thanks to Greg W. Gerstenberg for assisting in the bullfrog capture. The specimen and its prey have been deposited in the herpetology collection of the California Academy of Sciences (CAS 162076).

Submitted by **MARK R. JENNINGS,** Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118, USA ●

CAUDATA

AMBYSTOMA TIGRINUM CALIFORNIENSE (California Tiger Salamander). **PREDATION.** On 8 June 1986 at midday we saw an *A. t. californiense* larva swim out of a pond and wriggle onto land near the Hastings Natural History Reservation in Monterey County, California. A few seconds later, a *Clemmys marmorata* (western pond turtle) surfaced ca. 0.5 m away and looked around briefly before sinking below the water's survace. We believe that the salamander larva was attempting to avoid predation by the pond turtle. That evening, at the same site, we found a large (ca. 11 cm) adult *Rana aurora* (red-legged frog) that had just swallowed a larval *A. t. californiense.* This is the only known account of *R. aurora* preying upon *A. t. californiense.*

We would like to thank Harry W. Greene of the Museum of Vertebrate Zoology, University of California, Berkeley for his comments on an earlier version of the manuscript.

TARICHA TOROSA (California Newt). **CARRION ATTRACTION.** On 20 February 1984 I discovered the intact carcasses of two domestic cows in a remote portion of the Tuolumne River canyon in the foothills of the central Sierra Nevada, California. The site was an open grassy clearing 40 m from the river and a small tributary stream. Both carcasses were in full sunlight and the odor of putrefaction could be detected 30 m away. On one carcass a subadult *T. torosa* (64 mm SVL) was found crawling over the sternal region. On the other carcass I found two newts, a subadult (55 mm SVL) crawling back and forth over the front forelimbs, and an apparent female (68 mm SVL) resting in a shaded niche under the vertebral spine. To test the hypothesis of chance dispersion, the area within a 60 m diameter circle around the carcasses was searched; no additional newts were discovered. Next, the largest newt was moved one meter and released with its head pointing away from the carcass. It reoriented immediately and returned to its original position under the cow.

The newts were photographed and then observed continuously from 1030 to 1050 h during which time the largest newt did not move except when I disturbed it. The other two newts crawled with exaggerated locomotory movements and appeared to rub their ventral surfaces against the hairy hide of the carcasses. By 1230 h the carcasses had been in the sun for several hours and no newts were observed on or around them. I was unable to revisit the site but on 24 February

newts were still associated with the carcasses (Joe Medeiros, pers. comm.).

A search of the literature failed to reveal previous reports of terrestrial salamanders being attracted to carrion. Carcasses of large native mammals, especially mule deer, *Odocoileus hemionus*, are not rare in this part of the Sierra Nevada and represent an unpredictable but rich food source if they are infested by necrophagous fly maggots. However, none of the newts exhibited feeding behavior even though thousands of maggots were within a few centimeters in the mouths of both cows. Although it is possible that the newts had already fed and were satiated, I hypothesize that the newts were attracted by pheromones produced by other newts that had previously visited the carcasses or by a false chemical signal that mimicked newt sex attractant. My observations were made early in the breeding season when responsiveness to pheromones is strongest. The trance-like condition and ventral rubbing observed in two of the newts is similar to parts of the courtship behavior of *Taricha* described by Davis and Twitty (1964. Copeia 1964(4):601-610). Whatever the proximal cause of attraction, the detection and localization of putrefying carcasses should not present a significant physiological or behavioral hurdle for an organism with such dramatic chemosensory and orienteering capabilities (Twitty 1955. J. Exp. Zool. 129: 129-148; Grant et al. 1968. Science 160: 1354-1355).

Submitted by **STEVEN R. MOREY**, Department of Biology, University of California, Riverside, California 92521, USA ●

SAURIA

***ANOLIS LIMIFRONS*. PREDATION.** Although the small neotropical lizard *Anolis limifrons* is well studied, abundant, and thought to suffer high predation (Andrews and Rand 1982. *In:* Leigh, Rand, and Windsor, eds., The Ecology of a Tropical Rainforest, pp. 405-412), actual observations of predation on this species are rare. On 17 October 1985, we were collecting *Anolis limifrons* in forest near the Rio Aqua Salud of the Parque Nacional Soberania, Panama. Just after having captured a female from the base of a large tree, we noticed another lizard dart into a cavity at the base of a buttress, where it was pounced upon by a large spider (*Cupiennus* spp., Family Ctenidae). The spider successfully held the lizard as it struggled, retreated into a burrow with the lizard when we attempted to capture it, and only released the lizard when we began to excavate the burrow. When released, the lizard was unable to move, although it could pull its legs under itself when placed on the ground. It was dead within a half hour.

Birds, mammals, and snakes are the most obvious potential predators of *Anolis limifrons*, but this observation demonstrates that arachnids are also capable of taking adults of this species and may represent a significant source of mortality.

Submitted by **BRIAN C. BOCK** and **MANUEL QUINTERO**, Smithsonian Tropical Research Institute, Box 2072, Balboa, Panama. ●

***CNEMIDOPHORUS GULARIS GULARIS* (Texas Spotted Whiptail). REPRODUCTION.** On 1 May 1986, at 1750 h CDT we stopped at El Sauz, Starr Co., Texas, to search for syntopic contacts between *C. g. gularis* and the parthenogenetic *C. laredoensis*. Immediately upon leaving the vehicle mating behavior was observed between a male and female of *C. g. gularis* between Texas Farm Road 649 and dense growths of bunchgrasses. This behavior occurred in a microhabitat of scattered clumps of bunchgrasses between which were open sandy spaces free of debris (Fig. 1A). The mating sequence commenced when a male (estimated SVL between 65 and 72 mm) poked his head into the entrance of a freshly dug burrow (Fig. 1A, arrow), whereupon a female (estimated SVL between 64 and 69 mm) emerged from the burrow. The female moved a few cm from the burrow entrance; the male followed, assumed a position alongside the female, and placed his right forelimb over her body at the level of the axillary region (Fig. 1A). As the female continued to move slowly forward, the male kept pace undulating his pelvic region against the left flank of the female and occasionally vibrating his tail. The female remained docile and made no attempt to escape. As they moved ahead very slowly, the male positioned his pelvic region so as to alternately undulate it against the flank of the female and to rub the female's body with his cloaca (Fig. 1B). Using the right hindlimb as a counter balance, the male brought his cloaca into contact with the cloaca of the female (Fig. 1C). The male then very deliberately grasped the right flank of the female in his jaws and copulation with the right hemipenis was initiated. In Fig. 1D it can

SNAKES & LIZARDS
Their Care and Breeding in Captivity
John Coborn

An essential guide for anyone wishing to keep fascinating and exotic snakes and lizards

John Coborn draws on a wealth of experience to advise on the sensible selection and care of captive snakes and lizards. The high-quality illustrations, including a large number of excellent colour photographs make this a beautiful as well as informative book, invaluable for both the beginner and the experienced herpetologist.

The most popular and readily available species are described with notes on zoogeography and detailed information about indvidual requirements. The different kinds of terraria are carefully explained, with instructions for do-it-yourself accommodation. Every aspect of captive husbandry – heating, lighting, feeding, hygiene, veterinary care, lifespans etc – is explained in full.

The final chapter is devoted to captive breeding, particularly important in view of the pressing need to conserve species in the wild. The author describes the recent advances in knowledge and the most modern techniques, which make it possible for any enthusiast to start a breeding programme.

This practical and authoritative handbook will help you to maintain the health and well-being of any captive snakes and lizards – and create an attractive and unusual feature for your home.

The Author

John Coborn has made a lifetime study of zoological subjects – especially herpetology. He has been keeper, then curator, of reptiles and aquarium at a zoological park, and then moved on to be director of a zoological garden. He has organised several national and international herpetological symposia, founded a herpetological society, written many books and articles and made numerous appearances on radio and TV.

Figure 1A-D. Mating pair of *Cnemidophorus gularis gularis* at El Sauz, Starr Co., Texas.

be seen that the tail of the female is arched against the ground to neutralize the torsion effect produced by the position of the male. Following the assumption of the copulatory position, no well-defined movements of the mating pair were noted.

To gain information on the intensity of the act of copulation with reference to intrusive (i.e. threatening) stimuli, an attempt was made to slowly approach the pair as closely as possible after several minutes of observation. Although we decided not to collect the animals, both could have been easily captured (possibly by hand). Certainly, any number of predators could have captured them such was their mating intensity. *C. g. gularis* is ordinarily quite wary; the species can seldom be approached closer than 5-10 m.

In due course, the male released the female, possibly as a result of our intrusion, and slowly moved away stiff-legged, tail arched to the left, right hemipenis dragging in the sand, and disappeared into the stand of bunchgrasses. The female moved a few centimeters and disappeared into the burrow. This sequence was observed within 30-45 minutes of the end of the daily activity cycle in early May (CDT ca. 1800-1830), thus it does not appear that copulation in *C. g. gularis* is a lengthy process.

We know of no other instance of mating behavior in *Cnemidophorus* photographed under natural conditions. Lombard (1949. Copeia 1949:234) described an instance of copulation in *C. tigris* and Carpenter (1962. Amer. Midl. Nat. 67:132-151) described and diagrammed courtship in *C. sexlineatus*. Saxon (1968. Southwest. Nat. 13:54-55) photographed a copulating pair of captive *C. tesselatus* (involving a rare male) and Neaves (1971. Breviora 381:1-25) presented photographs showing captive male *C. inornatus* attempting to copulate with females of parthenogenetic forms. These descriptions are very similar to the behaviors we photographed at El Sauz suggesting courtship behavior is evolutionarily conservative in the genus *Cnemidophorus*.

***CORYTOPHANES CRISTATUS*. NESTING.** Field observations on the neotropical iguanid lizard *Corytophanes cristatus* are rare due to its apparent low population densities and cryptic morphology and behavior. At 1140 h on 25 June 1986, I encountered a female *C. cristatus* nesting on a trail along a ridgetop in primary wet tropical forest, ca. 600 m elevation, at Rara Avis, Heredia Province, Costa Rica. The female had already completed excavating the nest and oviposited five eggs. Her defensive behavior corresponded well to the description by Davis (1953. Fieldiana: Zoology 35:1-8) for captive lizards: She remained motionless until captured for measurement, but moved to the entrance of the nest when released, displaying laterally by expanding her nuchal crest and throat fan, and gaping and lunging during my attempts to measure the nest and eggs.

The nest was located in the middle of the trail, which contained less leaf litter than the surrounding forest but probably received comparable amounts of sunlight. The nest was ca. 50 mm in diameter and 95 mm in depth. The female measured 120 mm SVL and the top egg in the clutch mass was 20 mm in length, comparable to the values reported by Ream (1964. Herpetologica, 20:239-242) for a clutch laid by a captive female.

Interestingly, the vaulted anterior surface of the lizard's nuchal crest was caked with soil (Fig. 1). This may have resulted from her having wedged her head into the nest chamber during its construction, but another observation (J. Stout, pers. comm.) of a female *C. cristatus* nesting in a trail at the nearby La Selva Biological Station suggests that this structure may be actively employed as a scoop for excavation during nesting.

Thanks to A. Bien for providing accomodations and J. Stout for sharing her field observations.

Submitted by **BRIAN C. BOCK,** School for Field Studies, 376 Hale Street, Beverly, Massachusetts 01915, USA (Current address: Smithsonian Tropical Research Institute, Box 2072,. Balboa, Panama). ●

Figure 1. Female *Corytophanes cristatus* at the entrance to her nest, with soil visible in the depression of the anterior surface of her nuchal crest.

GEHYRA, HEMIDACTYLUS, AND ***NACTUS*** (Pacific Geckos). **EGGS AND HATCHLINGS.** These field and laboratory observations in Fiji and Tonga provide new information on the early life histories of several gecko species. *Gehyra oceanica* (Oceanic Gecko). Tonga

('Eua) - Eggs spherical; n = 7; dimensions $\bar{X}$ = 12.4x14.0 mm, range 12-13x12-15 mm; mass $\bar{X}$ = 1.25 g, range 1.1-1.5 g; hatchlings, hatched within 2 weeks in laboratory; SVL $\bar{X}$ = 33.7 mm, range 33-35 mm; caudal length (CL), $\bar{X}$ = 29.7 mm, range 28-32 mm; mass $\bar{X}$ = 0.83 g, range 0.75-0.92 g. Fiji (Viti Levu) - Eggs spherical; n = 4; dimensions $\bar{X}$ = 12.3x14.0 mm, range 12-13x13-15 mm; mass $\bar{X}$ = 1.18 g, range 1.1-1.3 g. Fiji (Rotuma) - Communal nesting, 23 eggs in palm axil, other communal clutches of 4, 10 and 15+ eggs; eggs spherical, hardshelled; n = 10; dimensions $\bar{X}$ = 12.5x13.5 mm, range 11.8-13.1x12.6-14.0 mm; mass $\bar{X}$ = 1.26 g, range 1.0-1.4 g; hatchlings, hatched within 2 weeks in lab; n = 4, SVL $\bar{X}$ = 33.6 mm, range 33. 1-34.2mm; CL $\bar{X}$ = 32.0 mm, range 29-34 mm; mass $\bar{X}$ = 0.9 g, range 0.8-1.0 g; hatched in May.

Gehyra vorax (Giant Oceanic Gecko). Fiji (Viti Levu) - Eggs spherical, hard-shelled; n = 2; dimensions $\bar{X}$ = 18x20 mm; mass = 3.9 g; laid in captivity 29 Dec. 1985.

Hemidactylus garnotii (Fox Gecko). Tonga ('Eua) - Eggs spherical; n = 1; dimensions 9x10 mm; mass 0.6 g; hatchlings, n = 3; SVL $\bar{X}$ = 27.3 mm range 27-28 mm; CL $\bar{X}$ = 20.0 mm, range 19-21 mm; mass $\bar{X}$ = 0.31 g, range 0.28-0.36.

Lepidodactylus lugubris (Mourning Gecko). Tonga ('Eua) - Hatchling, n = 1; SVL 25.0 mm; mass = 0.23 g. Fiji (Viti Levu) - Eggs spherical, hard-shelled; communal nest of 15 *lugubris* eggs (11 previously hatched) with 11 smaller ellipsoidal eggs (unidentified, ca. 5.6x7.5 mm, 9 previously hatched) beneath large horizontal rock slab, all glued to rock surface, found 15 June 1986; n = 2; dimensions $\bar{X}$ = 8.6x9.7 mm, range 8.5-8.7x9.5-9.9 mm; mass $\bar{X}$ = 0.4 g.

Nactus pelagicus (Pacific Slender-toed Gecko). Fiji (Viti Levu) - Eggs ellipsoidal, leathery-shelled; n = 5; dimensions $\bar{X}$ = 7.0x13.0 mm, range 6.5-8.0x12.0-14.0 mm; mass $\bar{X}$ = 0.44 g, range 0.39-0.49 g.

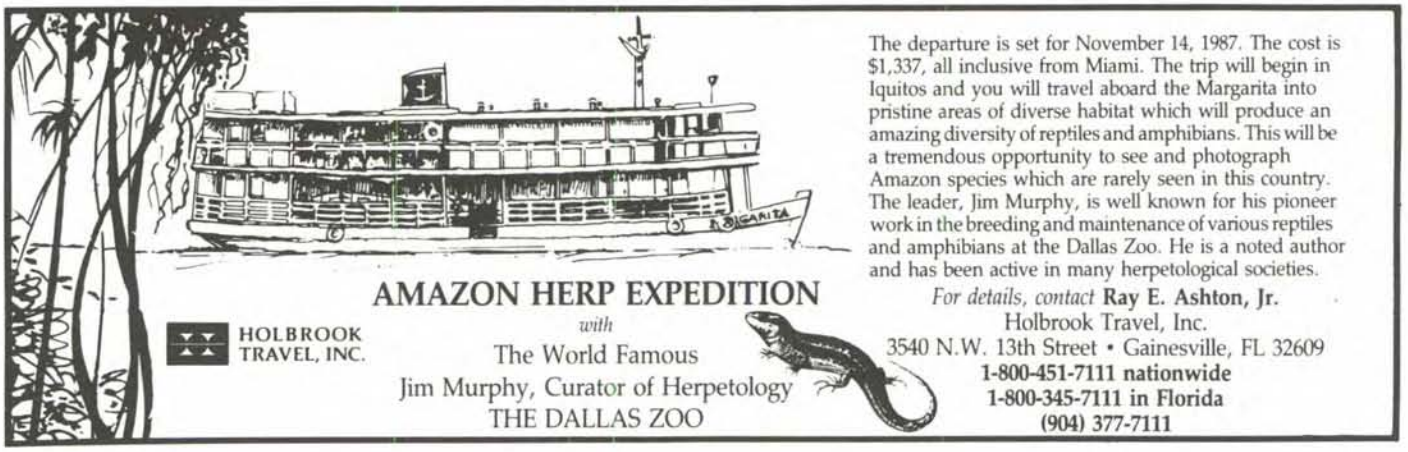
Submitted by **JOHN R. H. GIBBONS** (deceased), School of Natural Resources, The University of the South Pacific, Suva, Fiji, and **GEORGE R. ZUG,** Department of Vertebrate Zoology, National Museum of Natural History, Washington, DC 20560, USA ●

PTYCHOZOON LIONATUM (Gliding Gecko). **EGG GUARDING.** Egg guarding in geckos is apparently rare. Upon reviewing the literature only two references of such behavior could be found and both in reference to *Ailuronyx sechellensis* (Seychelles giant skin-sloughing gecko or bronze gecko) (High 197_.) The Natural History of the Seychelles, 64; McKeown and Miller 1984. 8th Ann. Reptile Symp. on Captive Propagation and Husbandry 96-101).

On 1 September 1985 a female gliding gecko, *Ptychozoon lionatum*, laid a clutch of two eggs on the side of her terrarium placed on display in the herpetarium at the Oklahoma City Zoo. Thereafter she could always be found in close proximity to the eggs and for relatively brief periods ranging from 15 minutes to an hour each day could be found with her tail and one hind leg draped over the eggs. Any attempt by the keeper to approach the eggs with his hand drew an immediate aggressive display—the female would rapidly approach the intruder with mouth opened. No physical contact with the keeper occurred. On several occasions, however, she was noted to drop with mouth-open onto the head of the leaf frogs (*Megophryes*) which ventured near the eggs. This behavior was repeated until the frog departed the area. Eleven subsequent clutches have been laid by this female, each followed by a similar egg-guarding behavior.

Submitted by **TIM TYTLE**, 12105 Camelot Drive, Oklahoma City, Oklahoma 73120 and **SCOTT WHEELER** and **DAVID GROW**, Herpetarium, Oklahoma City Zoo, 2101 N.W. 50th Street, Oklahoma City, Oklahoma 73111, USA ●

SERPENTES



EUNECTES MURINUS (Anaconda). **REPRODUCTION.** On 29 October 1986 we found a female *Eunectes murinus* in an open sunny site between fruit trees in an abandoned farm on the Rio Cuieiras (a tributary of the Rio Negro 60 km N Manaus, Amazonas, Brasil). The site was ca. 100 m from the river and an old shed skin and a large patch of dead grass nearby implied that the animal had been there a long time. When approached, the snake made no attempt to flee or attack. The snake (SVL 3.85 m TL 4.5m) (killed by a local inhabitant) contained 45 eggs ($\bar{X}$ mass = 400 g). Each egg contained a well developed embryo ($\bar{X}$ mass 34.2 g; X SVL = 34.4 cm; $\bar{X}$ TL 40.6 cm; n = 10). Clutch size is probably size dependent in snakes and this record falls between the clutch size given by Afranio do Amaral (1976. Serpentes do Brasil 2nd Ed., Editora da Universidade de São Paulo, São Paulo, 36 pp.) for *Eunectes*, who states "20-30 as normal, sometimes 40 or more," and Cunha and Nascimento (1978. Ofídios da Amazônia, Vol. 10, As Cobras da Região leste do Pará, Publ. Avulsas Mus. Paraense Emílio Goeldi 31:51) who state "around 70." We have not found any field records of clutch size in relation to adult body size for *Eunectes murinus*.

LAMPROPELTIS TRIANGULUM HONDURENSIS (Honduran Milk Snake). **MAXIMUM SIZE.** Williams (1978. Systematics and natural history of the American milk snake Publ. Biol. and Geol. No. 2 Milwaukee Public Museum, p. 50) cites 1228 mm TL as the maximum length of 23 males examined and 1512 mm TL the maximum of 18 females examined. A male, estimated to be 8 years old, died in my collection and was measured at 1496 mm SVL and 1702 mm TL, far surpassing Williams' measurements. The specimen was desposited in the Buffalo Museum of Science.

Submitted by **HENRY J. COHEN**, 24 St. Johns Pl., Buffalo, New York 14201, USA ●

OPHEODRYS VERNALIS (Smooth Green Snake). **BEHAVIOR.** The usefulness of behavior in establishing phylogenetic relationships is enhanced to the extent that some behaviors are shared by species known to be closely related. I here report a behavior exhibited by *Opheodrys vernalis*, rhythmic lateral head movement (RLH), previously described as a basic motor pattern of the congeneric *O. aestivus* (Goldsmith 1984. Southwest. Nat. 29:445-452). This behavior was performed by two captive *O. vernalis*, collected 24 July 1986 in Marinette Co., Wisconsin, on several occasions within several weeks of capture. As

observed by Goldsmith (*op. cit.*), RLH occurred both when snakes were moving and when stationary and at a rate of ca. once per second. RLH occurred in bouts that ranged from as few as 2-3 to over 20 back-and-forth movements, and it occurred with the anterior portion of the body both raised off of and in contact with the cage bottom. It was elicited whenever the snakes moved around the cage after being removed from cover and replaced on the cage bottom. Whether in this context RLH corresponded to a predator defense mechanism through mimicry of moving branches (Collins 1974. Amphibians and reptiles in Kansas. Univ. Kansas Mus. Nat. Hist., Pub. Ed. Series, No. 1, 283 pp.), or to enhancement of binocular vision (Henderson and Nickerson 1977. British J. Herpetol. 5:663-667; Henderson and Binder 1980. Milwaukee Publ. Mus., Contrib. Biol. Geol., No. 37, 38 pp.) during exploratory behavior, is unknown.

Since RLH has been reported for a number of unrelated genera of arboreal snakes (Henderson and Binder, op. cit.), this particular behavior is not necessarily diagnostic of taxonomic affinity. Interestingly, on the basis of its preference for open habitat (Smith 1961. Bull. Ill. Nat. Hist. Surv. 28, 298 pp.; Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Publ. Mus., Milwaukee, Wisconsin, 205 pp.; personal observation), *O. vernalis* probably is much less arboreal than *O. aestivus* or the other species for which RLH has been reported.

RHADINAEA MONTANA (Nuevo Leon Yellow-lipped Snake). **HABITAT.** On 18 July 1972 a single ♀ specimen of this species was collected at Ojo de Agua at Pablillo, Nuevo León, México at 2134 m near a spring under an imbedded rock in a marshy area along the edge of a ditch in a pine-oak habitat with cultivated fields nearby. The spring has been capped and an irrigation ditch leads to the fields and village. According to Myers (1974. Bull. Amer. Mus. Nat. Hist., 153(1):89-91) only four specimens of this species are known; nothing is recorded concerning elevations or habitats. The specimen was deposited in the collection of Ernest A. Liner (EAL 3095).

Submitted by **ERNEST A. LINER**, 310 Malibou Blvd., Houma, Louisiana 70364-2598 and **ALLAN H. CHANEY**, Department of Biology, Texas A & I University, Kingsville, Texas 78363, USA ●

TYPHLOPS MONENSIS (Mona Island Blind Snake). **PREDATION.** An adult *Typhlops monensis* (ca. 2.4 g; 175 mm SVL) was recovered from the bill of a snowy egret, *Egretta thula*, at Sardinera Beach, an altered portion of southern Mona Island, Puerto Rico. The snake was recovered after I pursued the bird for 2 minutes; the bird then dropped the specimen to the grass. This beach has more mesic and introduced vegetation than the rest of the island. The bird was discovered (on 21 July 1986 at 1544 h) at a shady location covered with grass, elevation ca. 5 m, on a partially cloudy day. The snake showed evidence of being bitten at both ends. The head was severely crushed, and portions of the body had lacerations probably caused by bites. The specimen has been deposited in the Museum of Biology of the University of Puerto Rico-Rio Piedras.

TESTUDINES

GRAPTEMYS GEOGRAPHICA (Map Turtle). **ADULT MORTALITY.** The Weaver Dunes, a sand prairie and Nature Conservancy preserve in Wabasha County, Minnesota, includes two nesting areas for turtles from adjacent wetlands. *Graptemys geographica* and *Chrysemys picta* from Halfmoon Lake, a backwater of the Upper Mississippi River, nest along the eastern edge (Section 8), whereas *C. picta* and *Emydoidea blandinqii* from wetlands along the Old Channel of the Zumbro River nest in the western portion (Section 7). During a herpetofaunal survey of the Weaver Dunes (Cochran 1986. Prairie Naturalist, in press), I collected evidence of mortality of nesting female *G. geographica* and *C. picta*.

From 10-15 June 1985, I found remains of 22 turtles (13 *Graptemys*, and 8 *Chrysemys*, 1 unidentified) in Section 8. Nineteen were in or near the oak savannah ecotone between open prairie and forest habitat just inside the crest of a ridge separating dunes and backwater; three were found in densely wooded habitat on the riverine side of the ridge from <1 m to 30 m from the water's edge. All turtles were found within a linear distance of roughly 500 m, but many were clumped within much smaller distances. For example, five turtles, including both species, were found within a distance of 20 m.

Only one dead turtle, a *Chrysemys picta*, was found in Section 7.

Dead turtles could be divided among three general classes of decomposition: (1) recent -shell completely articulated with scutes intact, insides hollowed out, but with scavenging insects still present and majority of inguinal and axillary skin in position (mortality presumably occurred during current year), (2) intermediate - shell partially disarticulated and scutes peeling [presumably mortality during the previous year, as Metcalf and Metcalf (1978. Herpetologica 35:93-96) indicate that exfoliation of scutes begins about four months after death] and (3) old - bones of shell bleached and largely disarticulated (mortality at least two years previously?). Not included in the counts above were occasional single weathered bones. All *Graptemys* in category (1) were identifiable as adult female *G. geographica*. Those in categories (2) and (3) could not all be identified but were most likely *G. geographica* based on known habitat and nesting habits.

Predation is the most likely cause for the observed mortality of nesting turtles. Although shells of turtles in category (1) were intact, heads and/or legs were removed, and surrounding grass and vegetation were sometimes matted down. Location of most turtles in edge habitat reflects a foraging pattern common to many predators. At least one family of foxes has denned within Section 8 in recent years; other potential predators include coyotes, raccoons, skunks, and opossums. The possibility remains that at least some mortality was due to another cause, such as thermal stress in the harsh sand prairie habitat, and was followed by scavenging.

Presence of turtles in several stages of decomposition suggests that predation has continued for at least several years. This conclusion is bolstered by a photograph of a bleached skeleton, identified as a *Chrysemys picta*, that appeared with a newspaper article on the Weaver Dunes in 1982 (Linsley 1982. St. Paul Dispatch, June 2, pp. 1A, 6A). Moreover, predation was not confined to the Nature Conservancy property. During summer, 1985, R. Vose (pers. comm.) observed over 10 dead *Graptemys* and *C. picta* on private land adjoining the southern end of the Nature Conservancy property (also in Section 8, but adjacent to a different backwater, Pritchard Lake).

This work was supported by a grant from the Minnesota Chapter of the Nature Conservancy.

ELECTRONIC MONITORING of REPTILES and AMPHIBIANS

For more than 16 years, Wildlife Materials technicians have helped biologists preserve threatened and endangered species. We adapt our telemetry systems to the habitat, behavior and body shape of any herp. Snakes, for instance, wear thin, light-weight implantable transmitters, while crocodiles and turtles carry a tracking device mounted on their backs or riveted to the scutes.

Electronic monitoring provides researchers with scientific samplings that
—identify habitat use and requirements
—register temperature to determine health and ovulation
—record behavior, from rest to slow movement to rapid action

An efficient telemetry system consists of a beeping, subminiature **transmitter**, waterproofed with beeswax and acrylic; a state-of-the-art **TRX-1000S Receiver**, which tracks up to 200 different frequencies simultaneously and which has a sophisticated noise-blanking circuit; a three-element folding directional **antenna** for signal reception over long distances and a loop **antenna** for picking up signals in a close, confined area.

TRX-1000S Receiver

subminiature transmitter has 2.4 x .9 x .4 cm dimensions

SERPENTES

LEPTOPHIS AHAETULLA PRAESTANS (Northern Green Frogger). MEXICO: OAXACA: Juchitán Dist: Palomares. December 1970. T. MacDougall. Verified by H. M. Smith. University of Colorado Museum (UCM 52510). New state record, southernmost record in México, extends range 115 km S of Isla Veracruz (Smith and Smith 1976. Synopsis of the Herpetofauna of Mexico, vol. 3:127, 201). The citation for Oaxaca in the latter work (under the name *Ahaetulla occidentalis)* was from Sumichrast (1873. Archs. Sci. Phys. Nat. 46:246) "This species (perhaps *A. occidentalis,* Gthr.) inhabits the western part of the isthmus of Tehuantepec" (translated from French). No state can be inferred with certainty from this statement, since the western part of the isthmus includes parts of both Oaxaca and Veracruz.

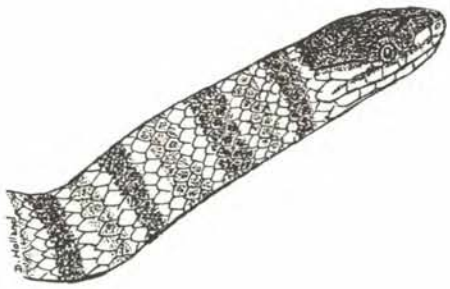
NOTEWORTHY RECORDS OF AMPHIBIANS AND REPTILES FROM TLAXCALA, MEXICO

The paucity of herpetological records from the Mexican State of Tlaxcala has been noted (Smith and Smith 1976, Synopsis of the Herpetofauna of Mexico., Vols. III and IV, John Johnson, N. Bennington, Vermont). These new records are based on specimens housed in the Colección Herpetológica, Instituto de Biología, Universidad Nacional Autónoma de México (IBH), and the Museo de Zoología "Alfonso L. Herrera," Facultad de Ciencias, UNAM (UNAM). All specimens were collected and verified by the authors.

PSEUDOEURYCEA CEPHALICA MANNI. Acopinalco del Peñón. 26 May 1979. (IBH 2894). First state record (Smith and Smith, 1976. Vol. IV).

PSEUDOEURYCEA LEPROSA. 3 km SW Tlaxco. 3 October 1976. (IBH 3084). Extends range 42 km N La Malinche (Sánchez de Tagle 1978. BS Thesis, Facultad de Ciencias, UNAM 91 pp.).

SPEA HAMMONDI MULTIPLICATA. 3 km WNW Tlaxcala City. 1 August 1976. (IBH 2955); 500 m SW Tlaxco. 3 October 1976. (IBH 2956); 4 km N Apizaco. 22 July 1979. (IBH 2957). New state record (Smith and Smith 1976. Vol. IV).



EUMECES BREVIROSTRIS BREVIROSTRIS. 3 km WNW Tlaxcala City. 1 August 1976. (IBH 3008); 4 km W El Carmen Tequexquitla. 20 October 1979. (IBH 3010); 3 km SSW Huamantla. 13 October 1979. (IBH 3009); San Lucas Tecopilco. 26 May 1979. (IBH 3011). New state record (Smith and Smith 1976. Vol. III).

CNEMIDOPHORUS ALPINUS. 3 km SSW Huamantla. 13 October 1979. (UNAM 744); 4 km W El Carmen Tequexquitla. 25 May 1979. (UNAM 742-743). New state record, extending the range 90 km W from the only reported locality (Maslin and Walker 1965. Univ. Colorado Studies Biol. Ser. 19:1-8).

CROTALUS INTERMEDIUS INTERMEDIUS. 3 km WNW Tlaxcala City. 8 August 1976. (IBH 3464-3465). First state record, extends the range 100 km W (Klauber 1972. Rattlesnakes. Vol. I, 2nd. Ed., Univ. California Press., Berkeley, Ca.; Armstrong and Murphy 1979. Spec. Publ. Univ. Kansas Mus. Nat. Hist., 5:1-88.; Campbell 1982. Southwestern. Nat. 27:353.).

CROTALUS SCUTULATUS SALVINI. Mpio. El Carmen Tequexquitla. 27 August 1985. (IBH 6128). First record near the type-locality since 1921 (Klauber 1972. op cit., Armstrong and Murphy 1979 op cit.).

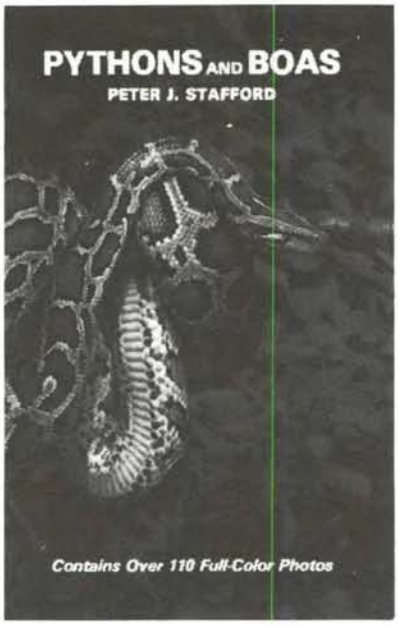
BOOK REVIEWS



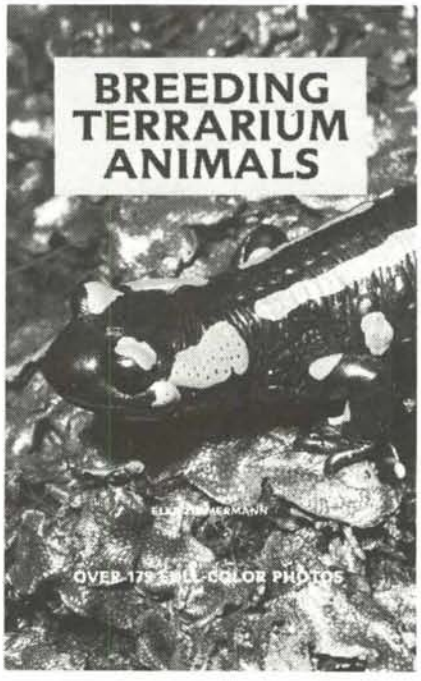
Biology of the Reptilia. Vol. 14, Development A, edited by Carl Gans, Frank Billett and Paul F. A. Maderson. 763 pp. Price $60.00, clothbound; Vol. 15, Development B, edited by Carl Gans and Frank Billett. 731 pp. Price $79.95, clothbound. 1985. John Wiley & Sons, New York.

I read these latest two volumes of *Biology of the Reptilia* during Super Bowl month last January. It didn't take me long to realize that the timing was more than mere coincidence. After attempting to tackle these enormous tomes—each one, at around 750 pages, is a Bear of a book—I now know what it must feel like to be a New England Patriot.

Biology of the Reptilia has come to represent an invaluable source of information for many topics of reptilian biology. The latest two contributions, encompassing any and all aspects of reptilian development that have been scientifically investigated, are worthy additions to the series. As stated explicitly in the preface to volume 14, a primary aim of these books is to address the paradox that, despite their morphological, physiological, and ecological diversity, reptiles as a group have been neglected in studies of major features of vertebrate development. Thus, while the editors have sought "to summarize the state of our knowledge of developmental pattern in this diverse group of organisms," and to identify "the major gaps that remain" (v. 14, p. vii), they also have taken on the task of promoting the increased use of reptiles by developmental biologists generally.

We learn early on how serious they are. For example, the introductory chapter to volume 14, authored by editors Billett, Gans, and Maderson, begins with an historical résumé of *Entwicklungsmechanik* and its tendency to ignore reptiles as experimental subjects. It soon focuses, however, on "practical considerations," which includes identification of interesting developmental phenomena that can be studied only in reptiles, such as temperature-dependent sex determination, appropriate species to use and their availability, and even recipes for various histological fixatives. Finally, the chapter closes with two

USEFUL NEW HERPETOLOGICAL TITLES FROM T.F.H.



***PYTHONS AND BOAS* • Peter J. Stafford**

Pythons and boas have long been among the most fascinating of snakes, and with continued encroachment upon their habitat they are now also among the most threatened. *Pythons and Boas* provides an up-to-date look at the Boidae, with emphasis being placed on the boids as threatened animals whose futures lie with increased captive breeding by concerned hobbyists. Every genus is covered, from the largest pythons to the smallest wood snakes, with summaries of what is known of their natural history and care in captivity. A special chapter spotlights methods of breeding boas and pythons in captivity. This volume includes the only available modern checklist of the species and subspecies of living boids, as well as a simple key to the genera. Heavily illustrated, with 111 color photos and numerous black and white illustrations and maps.

***BREEDING TERRARIUM ANIMALS* •**
Dr. Elke Zimmermann

Breeding Terrarium Animals provides the much-needed guidance to this often complicated phase of the terrarium hobby. The author presents her experiences and those of her colleagues in condensed but very readable form filled with information of use to hobbyists and professional herpetologists alike. Profusely illustrated in color, the book covers almost 100 species in detail, with basic information on dozens more. For the main species there are discussions of care, identification, and distribution, followed by detailed observations on the breeding behavior, incubation, and care of the young. The other species are grouped with the major species by their similarity in breeding behavior and listed with such essentials as number of eggs, incubation period, and temperature preference. In total, almost 350 species are covered, from axolotls to *Xenopus* among the amphibians and agamas to *Xantusia* among the reptiles. The discussions of the complicated life histories of the fascinating poison arrow frogs (*Dendrobates* and *Phyllobates*) are especially detailed. Good discussions of general terrarium maintenance, rearing food animals, and methods of egg incubation round out the book.

appendices—one listing sources of serial sections, the other listing the literature of normal development. This sets a pattern of comprehensive treatment and careful attention to detail that is generally characteristic of all that follows.

The two-volume set is organized around two themes, one taxonomic, one topical. Each major taxon is treated in at least one chapter that summarizes past developmental studies concerning that group; it also reviews known aspects of reproductive biology. Complementing these general chapters are a number of additional chapters that focus on particular topics that are particularly well studied. Volume 14 includes those chapters dealing primarily with turtles, crocodilians, and *Sphenodon;* volume 15 includes those for squamates, although reference to other reptiles is included at times. The following is a list of the chapter topics and authors. Volume 14: Introduction: Why Study Reptilian Development? (Billett, Gans, Maderson); Oocytes (Hubert); Turtles (Ewert); Marine Turtles (Miller); Crocodilians (Ferguson); The Tuatara (Moffat); Integument (Maderson); Immunity (Cooper, Klempau, Zapata); Pituitary (Pearson); volume 15: Squamata (Hubert); Lepidosaurian Reproduction (Saint Girons); Limbs and Embryonic Limb Reduction (Raynaud); Genital System (Raynaud, Pieau); Autotomy and Regeneration (Bellairs, Bryant); Parthenogenesis (Darevsky, Kupriyanova, Uzzell); Placentation and Gestation (Yaron); Ecological Aspects of Viviparity (Shine).

As would be expected of such a distinguished international array of researchers (and editors), all the treatments are of high quality. What distinguishes several chapters, however, and what makes these books much more than simply a catalogue or even a review of prior studies, is the wealth of significant and valuable data that are published here for the first time. For example, the two accounts of turtle embryology by Ewert and by Miller—which together span an impressive 254 pages—include a tremendous amount of previously unpublished descriptions of organogenesis, egg sizes, incubation periods, embryonic diapause and aestivation, and other subjects. Perhaps of interest to a wider range of biologists is Miller's presentation of an annotated, illustrated table of developmental stages from first cleavage (prior to oviposition) to hatching that is generally applicable to all marine turtles, and an analogous (albeit postoviposition) developmental table for crocodilians by Ferguson. Publication of these data represents a tremendous contribution to the embryology of non-squamates. Similarly, the extensive study of parthenogenesis in Eurasian *Lacerta* by Darevsky and colleagues, much of which is published in Russian journals (and typically written in Russian), is reviewed extensively in his chapter (co-authored by Kuprinova and Uzzell). This should be relished by those with a consuming interest in the general phenomenon of parthenogenesis, but who have been reared largely on a diet of North American *Cnemidophorus.*

Finally, these two volumes provide an opportunity to assess at least in a general sense the current state of reptilian developmental biology. Two aspects seem especially prominent. First, most of what is known about even the most fundamental aspects of reptilian development comes from study of only a relative handful of species, and much of this is exclusively descriptive. By the editors' own account, probably fewer than 100 of the 6,000 extant species, or less than 2 percent, have been studied in any respect. And while it is not reasonable to expect that every unstudied species has a novel pattern of gastrulation or limb chondrogenesis that will force revision of textbook descriptions of basic vertebrate development, it is also unfair to assume that no significant features remain to be discovered. The description of a novel pattern of gastrulation in the hylid frog *Gastrotheca* is an example of one such recent discovery in amphibians (del Pino and Elinson 1983). Certainly, consideration of additional species will bring handsome rewards. The fact that most of what has been done is descriptive can be attributed to most experimentalists having fixed on a very few species of typical "laboratory" vertebrates, none of which is a reptile. Admittedly, it is difficult to imagine reptilian subjects for developmental studies that could be more convenient than frogs which can be made to breed almost on cue and chick eggs which can be dialed up from your local hatchery. Nevertheless, the organ culture work of Raynaud, Ferguson, Maderson, and others clearly shows that this valuable procedure is feasible with reptiles, and perhaps easier than analogous methods for mammalian systems.

Second, the diversity of developmental phenomena documented in even the relatively few species studied poses a number of intriguing evolutionary questions that remain to be addressed. Contributing to the timeliness of these volumes is the fact that evolutionary biology in the last few years has witnessed a dominant interest in development, especially in the developmental mechanisms that underlie morphological transformation during phylogenesis. Some of the most dramatic transformations in vertebrates involve reptiles, thus the more that can be known about reptilian development, the better. As revealed by the comprehensive reviews provided in these volumes, a meaningful synergism between these two disciplines as applied to study of the evolution of reptiles remains largely in the future. Thanks to the latest installments of the *Biology of the Reptilia,* however, that day may now be closer at hand.

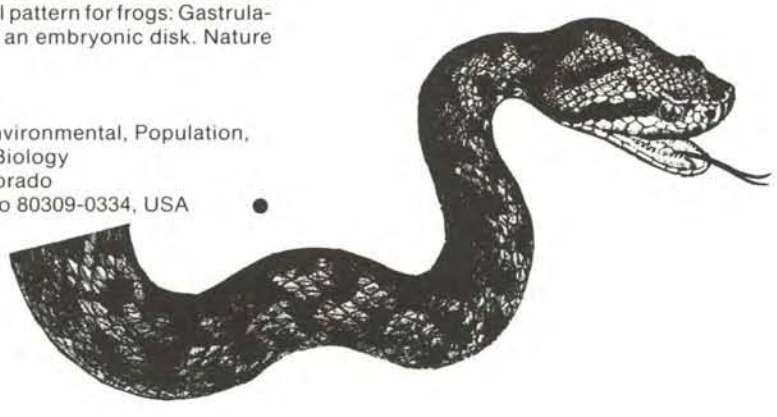
"A good source of general information and marvelous stories about reptiles and amphibians."—*Herpetologica*

Their Blood Runs Cold



Adventures with Reptiles and Amphibians

Whit Gibbons

Herpetologic lore, lively anecdotal humor, and conservation ethics are combined to provide entertaining, informative reading that conveys the challenge and excitement of scientific inquiry.

Paperback, $9.95t

The University of Alabama Press
P.O. Box 2877
Tuscaloosa, AL 35487-2877

The Snakes of Honduras, 2nd Edition, by Larry David Wilson and John R. Meyer. 1985. Milwaukee Public Museum (800 Wells St., Milwaukee, Wisconsin 53233), 150 pp., 124 figs. (20 in color), cover frontis (color); soft cover. $29.95 plus $1.50 shipping and handling.

In its 8½ x 11 in (21.6 x 27.7 cm) format, conforming in size with standard business stationery of this country, the excellent illustrations and double-column text of this seminal work are displayed to unusual advantage. Gross features include an excellent, scholarly 18-page essay, liberally illustrated, on the surprisingly complex environmental parameters of Honduras, embracing physiography, geological history, climate, vegetation and ecologic formations.

Keys and species accounts occupy the bulk of the book—109 pages— and are exceptionally useful in providing information on each species as a whole, as well as Honduran material, and critically evaluating the significance of that information. This section thus is of importance to the study of snakes of all adjacent regions, including northern South America, all of Central America, Mexico and even the United States; although based on but one small area (Honduras), the perspective extends far beyond those limits, making the study a reference work of exceptionally broad usefulness and influence.

Excellent as the two preceding sections are, the third, entitled "Present-day Distributional Patterns," is the apogee of scholarship in this remarkable work. Methods of statistical analysis are applied to determine correlation between distribution and physiographic region, ecological formations and elevation, revealing eleven broad distributional patterns of Honduran snake species. Impressive also are the lengthy tables specifying the distribution of each snake species with physiographic regions, ecological formations and elevation.

The information provided in this work indicates a remarkably complete knowledge of the snakes of Honduras; certainly the level of analysis is far better than for any other country in the Americas. Yet all is not known, even yet; the authors point out that the Montane Rainforest (of Cerro Santa Bárbara and possibly Cerro Cangrejal) is "virtually unknown" ophidiologically, and two physiographic regions (the Motagua Plain and the Aguán-Negro Plain) are "virtually or totally unknown." Another unknown, despite all of the species-oriented correlation already completed, is the extent of geographic correlation found in intraspecific variation.

Beautifully executed and scholarly though this work is, indeed setting a new, remarkably high standard for faunistic studies, much remains to be done before the subject is exhausted, as the authors make clear. The present step is nevertheless uniquely noble.

Generally, scientific publications are content to reveal scientific erudition insofar as the talents and labors of their authors permit; it is the accepted norm to be detachedly impersonal. It is both refreshing and sobering that Wilson was willing to put a bit of his other self into this work, and the editors to accept it, even briefly, in a compellingly eloquent preface, and in a few other introductory paragraphs as well where the sentimentality of a sensitive, caring person comes hauntingly through to the reader. The book was not produced by a sophisticated machine. One wishes that the author's voice could be amplified and multiplied many times over, for his goal is the vision of all who can see beyond the thickets of personal, immediate concern but who have had little power to convert vision to reality.

As the second edition of a work first appearing in 1982, the 1985 version maintains the earlier-established, basic framework, with numerous superimposed modifications throughout, primarily involving 21 excellent color photographs by Louis Porras and Jim Bridges (unfortunately not including the splendid portrait of *Bothrops schlegeli* that graced the cover of the first edition). The number of species dealt with was increased from 91 to 95, and the discussion of systematics of numerous species was revised. Thus the work constitutes an invaluable reference work providing a concise overview of the present state of knowledge for every species treated—a veritable gold mine of current knowledge and sources thereof.

Accordingly, it is incumbent upon everyone who has benefited from the first edition to acquire the second, even with the misgiving that before long a third edition may well be along. And even more importantly, anyone interested in any regional biotic study, or in the broader problems of Central America, who have not profited from the first edition, should not miss the second.

HOBART M. SMITH
Environmental, Population and Organismic Biology
University of Colorado
Boulder, Colorado 80309-0334, USA

Lions and Tigers and Bears. A Guide to Zoological Parks, Visitor Farms, Nature Centers, and Marine Life Displays in the United States and Canada, by Jefferson G. Ulmer and Susan Gower. 1985, Garland Publishing, Inc., New York. 230 pp. $20.

The only thing missing from the title is "Oh, my!" This book is merely an assemblage of U.S. and Canadian facilities which exhibit live animals. The main body contains a listing of over 850 zoos, parks and display areas alphabetically by state and cities within the state. Canadian listings follow those of the U.S. Compilations appear to be summaries of questionnaire forms submitted to all the listed attractions. The listings are in typewriter type, which, for this kind of book, is probably adequate.

Some information regarding individual facilities is misleading. The Cleveland Metroparks Zoo, for instance, is reported to have a saltwater aquarium (which it didn't at the time the book was published) and reptiles (no reptile house and only a few turtles and tortoises mixed in with other exhibits.) The hours for the CMZ were given as 9 - 5 daily (correct) and 9 - 7 in summer (The only day the zoo is open to 7 is Sunday.) If this entry is any indication as to the validity of the others, the book is highly suspect as to its overall accuracy.

The best information is contained in the visitor notes section of the preface. Sound advice that should be well taken includes the type of clothing to wear: "Dress in loose comfortable clothes and a well-broken-in pair of walking shoes or lightweight boots. Add rain gear, sweaters, coats, gloves, and other foul-weather items as the climate requires." Another sound suggestion: "Although some zoos permit the admittance of household pets, it is generally a good idea *not* to bring them to any zoo/park area; pets can spread diseases to other animals and cause unnecessary disturbances." I love this paragraph: "Have your group leave radios, alcoholic beverages, smoking materials, and other non-essentials outside of the zoo/park area—these items are generally unwelcome (and often prohibited) on zoo/park grounds. DO bring cameras, binoculars, notebooks, field guides, and your teeming, unaltered senses, ready for a day of natural excitement!"

In the general information section of the preface, items covered include what kinds of guest facilities may be found in zoos/parks, the possibility of educational programs offered to teachers and students; and the suggestion that if a trip is planned for large groups it is almost mandatory to write or call well ahead of the visit for any special arrangements that are to be made in advance.

Also in the general information section many special zoo and park words and terms are defined for the edification of the non-zoological lay person. Among these are "docent," "braille-sensory exhibits," "native animals," and "wildlife rehabilitation programs."

And then what follows in the main body of the book is about as interesting as reading the dictionary. The litany of entries begins with the Birmingham, Alabama Zoo and concludes 218 pages later with Swan Lake—not the ballet, but the Christmas Hill Nature Sanctuary in Victoria, British Columbia. In between is information guaranteed to be obsolete faster than a Guinness Book of Records entry. It will certainly be obsolete long before the book's acid-free 250 year life paper deteriorates. A number of black and white animal photos break up the monotony of the written material.

Visitors to the various facilities listed would get up-to-date information by writing or calling; nearly all public zoos and other animal parks have colorful informational brochures available free to anyone. A 22¢ stamp would be a slightly better investment than the $20.00 price of LIONS AND TIGERS AND BEARS. Oh, my!

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1987

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Herpetological Review

Volume 18 March 1987 Number 1

1987 JOINT ANNUAL MEETING

The 30th Annual Meeting of

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

and The 35th Annual Meeting of

THE HERPETOLOGISTS' LEAGUE

with

The 2nd Annual Meeting of

EL COMITE NACIONAL HERPETOLOGICO, MEXICO

HOSTED BY EL INSTITUTO DE BIOLOGIA, U.N.A.M

in

Veracruz, Veracruz, Mexico

9-15 August 1987

Universidad Nacional Autonoma de Mexico was established in 1910. It now has 308,000 students and an academic staff of 30,000, 1700 of which are devoted to scientific research. The university has branches throughout Mexico. The largest branch, known as "Ciudad Universitaria," (CU) is in Mexico City, covering 733 hectares on a lava flow at the southern edge of the city.

In 1929 the Institute of Biology was formed. There are now 14 institutes and seven centers for scientific investigation. The primary function of these institutes and centers is research, integrated with teaching. Other departments and faculties within UNAM are primarily devoted to teaching and offer degrees at the bachelors, masters, and doctoral levels. Within the Institute of Biology a doctoral program in ecology is offered.

The Institute of Biology at the present time consists of three departments: Botany, Ecology, and Zoology. There are also the field stations of Chamela in Jalisco and Los Tuxtlas in Veracruz, and the Botanical Garden in Mexico City. A total of 150 academic staff comprise the Institute of Biology. Included in this group are nine herpetologists, five investigators and four technicians.

Meeting Site

The meeting will be held in Veracruz, Veracruz at Hotel Mocambo, a large sprawling Spanish style hotel located 300 m from the beach on the Gulf of Mexico. Average daily temperatures and humidities are lower than they were for either Tampa or Springfield and the possibility of drenching thunderstorms is also less likely in August. Veracruz is a pleasant tropical port city with a population of 300,000. Mocambo is located at the south end of the city, a direct 10 min from the airport by taxi. Housing, meals, papers, and social sessions all will be in the Hotel Mocambo complex. Paper sessions will be held in air conditioned rooms.

Registration

The registration fees are $30 regular, $15 student or spouse/guest. This includes the meeting costs, refreshments for the breaks, the registration social, the Monday night wine and cheese social, the BBQ and chile cookoff, live musical groups, and refreshments at the auction. Only persons with name badges will be admitted to the social or scientific events. The spouse/guest category is provided for persons accompanying regular members or student members and who will NOT be attending the paper sessions.

Anyone registering after May 1 will be charged an additional $15. Exceptions will be made for all attendees coming from countries where it is difficult to obtain funds in US $ or Pesos Mexicanos. They can pay at the meeting registration desk IF they have sent in the preregistration forms and requested a waiver. Fees may be paid in either US $ or Pesos Mexicanos at the current rate of exchange.

Currency

Mexico's currency is the peso, and the current rate is $850 per dollar US. Inflation and fluctuation of the peso according to the world petroleum prices make it impossible to guarantee prices in pesos. VISA, Mastercard, American Express, Bancomer, Banamex, Carnet, and Diners cards are accepted at most major hotels and restaurants. Foreign checks on US banks will be accepted for registration fees and prepayment of hotels and meals. Travelers checks, credit cards, Pesos Mexicanos, US $, international money orders, or checks drawn on Mexican banks will be accepted at the meeting site. Money can be changed in the banks at the Mexico City airport or at the meeting site, no problem.

Transportation

AIR: Make your reservations to Veracruz, Veracruz. There is only one airport. Ray Ashton is "handling" discount airfares from the USA to Veracruz through the travel agency:

Holbrook Travel, Inc.
3540 N.W. 13th Street
Gainesville, FL 32609, USA

Call Toll Free: in Florida 1-800-345-7111, other states 1-800-451-7111

When calling, identify yourself as one of "those" wanting bargain rates to the SSAR-HL conference. Ray lists roundtrip fares from 11 major USA cities to Veracruz (with a transfer in Mexico City) ranging from $296 (Miami) to $458 (Seattle).

BUS: ADO and AU offer first class bus service to Veracruz from Mexico City as well as border towns. Second and third class buses also are available.
PRIVATE VEHICLE: The roads from Laredo or Brownsville, Texas provide a scenic direct route to Veracruz. Hotel Mocambo is located on the main highway at the south edge of Veracruz.

In order to enter Mexico, it is necessary to have TWO documents: A current passport OR a notarized copy of a birth certificate; AND a driver's license with photograph OR a voter's registration card.
TAXI: Free shuttle service will be available from the airport to Mocambo on Saturday and Sunday. Present taxi rates are $2.50 US/person from the airport to Mocambo.
TRAIN: Train service is available from Mexico City to Veracruz, providing many hours to view the scenic countryside. However it is not recommended for the unadventurous.
RENTAL VEHICLES: International rental agencies have offices at the airport on Mexico City and in Veracruz (Avis, Hertz, National). VW bugs are the most common and economical way to go, but VW buses and larger cars may also be rented.

Housing and Food

Hotel Mocambo is offering a package rate of six nights with meals (five breakfasts, four dinners, one supper) for a special price of $200 US per person (double occupancy) or $250 (single occupancy). Meals only are $60. Meals will be served buffet style, with a large selection of regional cuisine for all palates. (We will have total control of the menu, water and disinfecting of vegetables for those concerned about such things.) The midday meal, also buffet style featuring local seafood, will be served as the large meal of the day. All other meals, except the Thursday night fiesta, are paid for in your registration fee. Meals may be purchased separately or in the many inexpensive seafood restaurants and taco stands located on the beach within 5 min walking distance of Mocambo. Veracruz has hundreds of restaurants; a complete restaurant guide will be provided at the registration desk.

Rooms without meals are $35 single or $18 per person double occupancy. The rooms are deluxe—air conditioning, private shower with hot and cold water, private bathroom, cable TV, telephone, room service. The entire Hotel Mocambo complex has been reserved for this meeting, including tennis courts, swimming pools, jacuzzi, and bars, but space is limited to 140 rooms. The rooms will be filled by those registering promptly.

Meeting registration & housing reservation forms are included with the final call for papers (see below). But don't worry if you are late in registering. Ample space has been reserved at five hotels within easy staggering distance of Mocambo (within 500 m). Veracruz has hundreds of other hotels, motels, and hostels ranging in price from $3-50 per night, depending on your customs. If you have a special need, write. We are sure to be able to satisfy nearly everybody in Veracruz in their quest for economy and comfort.

Camping

Two camping—trailer parks are located within 2 km of Hotel Mocambo. Both have bathrooms, showers, and full hookups. Present rates are $.25 per day per person. These are within 10 min walking time (for Society officers).

Parking

If you drive or rent a vehicle, no problem. Free parking with security guard is available at Mocambo.

Business Meetings

Inter-society Liaison Committee—1930, Aug. 8 Room B
SSAR Board Meeting—1000, Aug. 9 Rm. B
HL Board Meeting—1300, Aug. 9 Room C
Inter-society Liaison Committee Meeting—1300, Aug. 12 Room C
SSAR Business Meeting—1730, Aug. 13 Room A
HL Business Meeting—1730, Aug. 14 Rm. A

Collecting

Collecting is discouraged by the SSAR, the HL, the CNH, and the organizers of this meeting. It is illegal to collect, possess or transport Mexican wildlife without a permit. Attendees are asked not to bring live reptiles or amphibians onto the meeting grounds unless this has been previously cleared with the meeting co-chairpersons in writing. Permits may be obtained to collect reptiles and amphibians for scientific purposes. Application procedures appear below.

Scientific Sessions

HL Distinguished Herpetologist Lecture: Henry Fitch

CNH Invited Speaker: Miguel Alvarez del Toro (Tentative)

Call for Papers. The final call for papers was mailed to all members in January. Deadline for the receipt of abstracts *and* preregistration is 1 May 1987. Abstracts will not be accepted unless accompanied by the preregistration fee (except for those speakers from countries where there is a problem transferring currency, and who request to pay on site). Papers "by title only" are no longer accepted. Papers may be presented in either English or Español. If time and space become limited, papers will be scheduled in order of receipt. Papers will be limited to 12 min for presentation and three min for discussion.

Poster Sessions. Posters do not have to be limited to flat presentations to hang on walls. Be innovative. We will try to accommodate even the wildest ideas with the resources we have available.

Awards

The Herpetologists' League will make awards ($$) for the Best Student Paper and the Best Student Poster.

EXTRA SPECIAL ACTIVITIES

Herpetological Art and Photo exhibit. All those wishing to display materials are welcome to do so. Please bring all exhibits mounted and ready to hang.

Photo Contest (new this year, sponsored by the CNH).
Theme: Neotropical Reptiles and Amphibians.
Format: Color prints, 8 x 10 in ONLY (no other sizes), mounted on neutral colored mounting board 11 x 14 in.
Prize Categories: Turtles, Snakes, Lizards, Anurans, Salamanders, Other (Dinosaurs, Crocodilians, Caecilians, Herpetologists in compromising positions, etc.) Prizes will be awarded in each category.
Limit: Three photos per registrant (total regardless of category). Bring your mounted photos to the registration desk. Photos will be exhibited throughout the meeting.

Herpetological Exam. Marty Crump has again agreed to coordinate this ever-popular event to test your knowledge of the field of herpetology. This year's exam will feature neotropical herps and will be available in Spanish and English versions. Prizes will be awarded to the winners, and proceeds will be used to support the SSAR Grants-in-Herpetology program.

Exhibits. The foyer of Hotel Mocambo will provide a congenial and convenient locality for commercial exhibitors. For exhibit applications or further information, contact:

Ruth Zantzinger
2108 Cherry Street
Philadelphia, Pennsylvania 19103, USA
Tel. (215) 557-0182

Socials and other Special Events

Sunday: Registration social with tropical entertainment.

Monday Night: Wine and cheese social.

Tuesday Night: Auction (Sponsored by SSAR). Now a tradition, Joseph T. Collins will again coordinate the auctioning of herpetological items. Please bring or send all items to be donated. A tax-deductible receipt will be given for all donations. Complimentary beverages will be provided throughout the auction.

Wednesday Night: Mexican beach barbecue with a chile con carne cookoff with music by a marimba group. Film: Tropical rainforest in Mexico. Synchronized slide presentation on Estacion de Biologia Los Tuxtlas.

Thursday Night: Seafood extravaganza with entertainment provided by Universidad Veracruzana Ballet Folklorico. ($10.)

Friday: Field Trips.
Mt. Orizaba to observe salamanders
The wetlands of Lerdo de Tejada to observe turtles
Volcan Santa Martha to observe cloud forest herps
Estacion de Biologia Los Tuxtlas to observe neotropical forest and wetland reptiles and amphibians

In addition a SCUBA diving trip is planned for the coral reef off the coast of Veracruz. A diving excursion to Puerto Morelos, Quintana Roo can also be easily arranged.

Family Entertainment

Bilingual guides will be available throughout the week for shopping tours to the local

markets, trips to museums, historical sites (San Juan de Ulua—prison of the Spanish Inquisition; first Catholic church in the New World), archeological sites, and aquarium. No guides will be necessary to reach the beach.

Live Exhibits

We will not have all Mexican species represented, but we will have the largest display ever presented at an SSAR/HL meeting. Natural backgrounds will be available for photography.

Collections

Anyone wishing to examine specimens at any of the collections in Mexico should make prior arrangements with the curators to do so before or after the meeting, not during the meeting.

DEADLINES

May 1: Abstracts and résumés of all papers and posters.
Preregistration payment for those submitting papers.
Preregistration payment for those not wishing to pay an extra late registration fee of $15.
Housing registration and meal package registration.

August 1: Final day for 80% refund of registration fees.

REGULATIONS TO OBTAIN SCIENTIFIC COLLECTING PERMITS FOR MEXICAN WILDLIFE

Many investigators have inquired about the procedures for obtaining collecting permits so they may collect specimens while in Mexico for the SSAR/HL meeting in August. The following information should answer all such questions.

Investigators must send **all** of the required material, without exception, to the embassy of your country in Mexico City. The embassy must certify the documents and send them to:

Direccion General de Conservacion
Ecologica de Los Recursos Naturales
Rio Elba #20 - 8o Piso
Col. Cuauhtemoc.
06500 Mexico, D.F.

The required documents consist of:

1) Letter of support from your institution certifying the proposed research and/or collecting.

2) Letter certifying that you agree to pay the expenses of a Mexican technician during the field work in Mexico. (This gives Mexican students a chance to learn with professionals, establishes contacts both for the foreign investigator as well as the Mexican student, and makes it easier for the project to function logistically).

3) Letter from a Mexican institution or investigator endorsing the project.

4) Curriculum vitae of investigator and two passport size photographs.

5) Copy of project proposal with justification of why you need to collect the animals and how you are going to do it.

The project proposal needs to include:

a) Common and scientific names of all species to be collected (even if you do not know which species occur in an area you must at least include a hypothetical list or your proposal will not be considered) and the number of individuals of each species.
b) Collecting and transporting methods. If you plan to tag animals you must include a list of the types of tags to be used and the number series.
c) Localities where the investigations or collecting are to be carried out.
d) Period of investigation or collection (exact starting and ending dates).
e) Locality where you will be leaving Mexico (which border town or airport).

When the collecting permit is approved La Direccion General de Conservacion Ecologica de los Recursos Naturales will send a telegram to the investigator informing him or her of acceptance and requesting an international money order for the amount specified according to the Ley Federal de Derechos Vigente. (This amount is subject to change so no amount can be stated at this time.)

If permission is granted to collect or study Mexican wildlife for scientific purposes the investigator must comply with the following regulations:

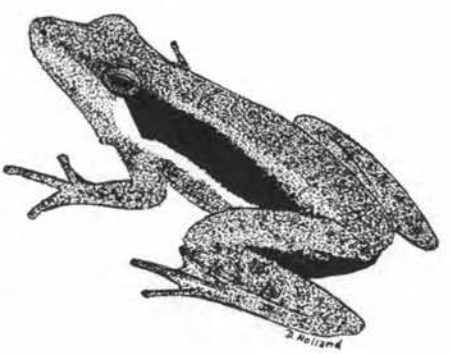
1) Deposit 40% of the total of the specimens collected, properly preserved and with the collecting data, in one of the Mexican scientific institutions dictated by the DIRECCION GENERAL DE CONSERVACION ECOLOGICA DE LOS RECURSOS NATURALES.

2) Establish contact with the delegates of SEDUE in the states where you are to make the investigation or collection.

3) Comply with the regulations required by LA DIRECCION GENERAL DE SANIDAD Y PROTECCION AGROPECUARIA Y FORESTAL DE LA SARH for the exportation of live animals.

4) Once the field work is completed you must send within 30 days to DIRECCION GENERAL DE CONSERVACION ECOLOGICA DE LOS RECURSOS NATURALES a copy of the results of the field work in the format of the approved project and a copy of the field book listing the specimens collected. When the data are published, reprints of the scientific articles resulting from the investigation must also be sent.

ABSOLUTELY IMPORTANT



ALL OF THE REQUIRED DOCUMENTS, INCLUDING DIPLOMATIC CERTIFICATION FROM YOUR EMBASSY, MUST BE RECEIVED BY THE DIRECCION GENERAL DE CONSERVACION ECOLOGICA DE LOS RECURSOS NATURALES AT LEAST 30 DAYS PRIOR TO THE STARTING DATE OF THE PROPOSED INVESTIGATION OR COLLECTING, OR THE STARTING DATE *WILL* BE DELAYED.

The above is the latest material I personally received from SEDUE (2 December 1986). Please note the emphasis in the requirements for granting permission to collect for SCIENTIFIC INVESTIGATION. General collecting for museums or personal collections is not endorsed and permits for such activities will not be issued. Because of past abuses by both scientists and hobbyists as well as by representatives of biological supply houses, the regulations are set up as they are. They are not done to intimidate individuals or to prevent legitimate scientific investigation or collecting in Mexico but to protect the native fauna and discourage the abuses that occurred in the past.

RICHARD C. VOGT ●

SPONSORSHIP OF NON-U.S. MEMBERS

SSAR is expanding its sponsorship of non-U.S. members by requesting contributions to a fund established to defray the membership dues of herpetologists in countries that face difficulties with exchange of foreign currency. We encourage your participation in this program. Please contact our Treasurer, Dr. Henri C. Seibert, if you can assist in the identification of colleagues who can benefit from this program. ●

SSAR BUSINESS

SSAR CONTRIBUTORS

Once again we are pleased to recognize those individuals who have financially aided the Society by becoming Contributing or Sustaining members for the year 1986 and also those who have supported the Grants-in-Herpetology fund. A statistical analysis would reveal a very high positive correlation between those who have contributed in 1986 and those who have contributed in previous years. To all of you, new or old, we offer our thank you. H.C. Siebert, Treasurer.

SSAR ELECTION RESULTS

The results of the 1986 SSAR Election are as follows:

President-elect: Hugh R. Quinn
Secretary: James S. Jacob
Treasurer: Henri Seibert
Board - Regular: Lynne Houck
Board - Non-U.S.: James P. Bogart

A total of 508 members voted in this election. The vote for president-elect was a tie between the two candidates, and the final decision was made by the Board of Directors.

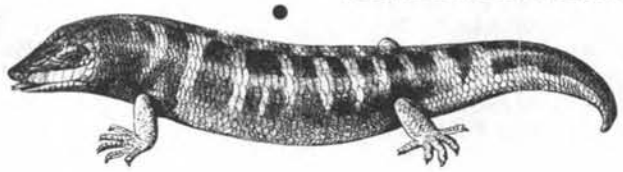
The Society extends its gratitude to the Nominating Committee (Hugh R. Quinn, Chair) and to the SSAR Elector (J. Eric Juterbock) for their hard work, and to the outgoing President and Board Members for their service during their terms. ●

SSAR PROGRAMS FOR REGIONAL HERPETOLOGICAL SOCIETIES

The SSAR has developed three new programs to promote interactions between it and regional herpetological societies and to enhance the membership of both.

1. Individuals who join the SSAR *through their regional society* will have $2 of their SSAR dues credited to to their own society's treasury. This program is designed to encourage people to join the largest and most diverse international herpetological society, to enhance the membership of the SSAR, and to reward regional herpetological societies for participating in the program.

2. Regional herpetological societies are now eligible for a 25% discount on all orders of $30 or more for SSAR publications. This discount may only be applied to post-publication prices and is valid during the calendar year 1987. Orders must be placed by an officer of the regional society.



3. Two sets of plates from the new SSAR book **Turtles of Venezuela** have been sent to each regional society in the USA. The plates may be sold, auctioned, given away as prizes, or used in any other way deemed appropriate by the regional society officers.

Officers of all regional herpetological societies in the USA have been sent detailed information about these programs. This information is available to anybody who requests it.

STEPHEN HAMMACK
Regional Societies Liaison Chairman ●

CRESTED IGUANA DISCOVERER DIES

We regret to report that John R.H. Gibbons, discoverer of the Fijian crested iguana, and his family drowned in a boating accident on 15 November 1986. His friends, colleagues and the entire herpetological community mourn the loss of Dr. Gibbons and his family. ●

NEWSNOTES

VOLUNTEER PROGRAM AT AMNH SOUTHWESTERN RESEARCH STATION

Approximately 20 volunteer positions are open in 1987 at the Southwestern Research Station of the American Museum of Natural History in Portal, Arizona. The volunteer program is run annually and offers students in the biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging at the Station are provided to volunteers in exchange for four hours per day of routine work chores, with the remaining time available for research activities.

Volunteers are needed between 10 March and 1 December and are appointed for part of this period, with a minimum appointment of four to six weeks. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

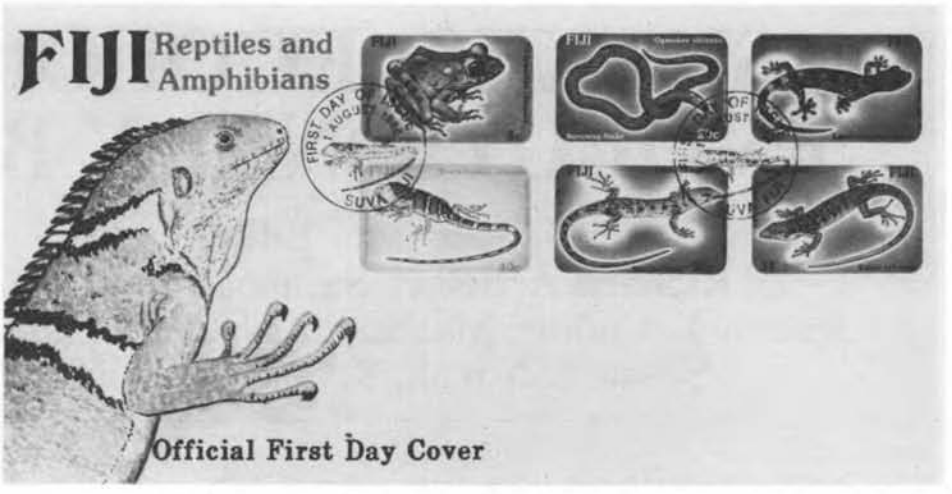
Applicants for positions from March through May should submit forms by 15 February, summer volunteers, June through September, by 1 April. The program is open to both undergraduate and graduate students, who may pursue their own research projects.

For application forms, write: Resident Director, Southwestern Research Station of The American Museum of Natural History, Portal, Arizona 85632, USA. (602) 558-2396 ●

EUTHANASIA OF REPTILES AND AMPHIBIANS

The Universities Federation for Animal Welfare and the World Society for the Protection of Animals have formed a Working Party on Reptiles and Amphibians. The aim of this group is to collate and disseminate information on the humane euthanasia of amphibians and reptiles.

Persons having information on this subject, in the form of technical data or individual experiences, are asked to write to: U.F.A.W., 8 Hamilton Close, Potters Bar, Herts EN6 3QD, England. ●



WISCONSIN HERP SPECIMEN RECORDS WANTED

If you maintain a collection of preserved amphibian or reptile specimens from Wisconsin, please send a listing of these specimens to me (if you have not already done so). Include locality data and collection date. We are collecting and verifying all Wisconsin specimen records as part of an intensive survey of amphibian and reptile distribution in Wisconsin. Send to Gary S. Casper, Section of Vertebrate Zoology, Milwaukee Public Museum, Milwaukee, Wisconsin 53233, USA ●

VOLUNTEERS SOUGHT FOR SEA TURTLE TAGGING PROJECT

The Caribbean Conservation Corporation, Inc., managers of the Green Turtle Research Station in Tortuguero, Costa Rica, is seeking volunteers to help with the sea turtle tagging project for the 1987 season. Departures for the 13 day program, including a trip to the Monteverde cloud forest, are: July 6, 13, 20, 27, August 3, 10, 17, 24. The cost of this tax deductible research travel program is $1,395, all inclusive from Miami. Volunteers will work with the research team as they tag and collect data on nesting green, hawksbill, and leatherback turtles.

Arrangements for volunteers are being made by Holbrook Travel, Inc. For an application or further information, contact: Ray E. Ashton, Jr., Holbrook Travel, Inc., 3540 N.W. 13th Street, Gainesville, FL 32609. Or call 1-800-451-7111 (in Florida, 1-800-345-7111). ●

CRESTED IGUANA STAMP

The Crested Iguana, an exquisite new species first described in *Journal of Herpetology* in 1981, is featured on a 40¢ stamp issued 1 August 1985 by the Fiji Government. This is part of a set of 6 stamps on Fiji reptiles and amphibians available from Philatelic Bureau, G. P. O. Box 100, Suva, Fiji. Prices for set: F$2.43 mint or cancelled, F$2.67 first day cover (approximate conversion rate F$1.03 = US $1.00); use International Money Order, payable to Postmaster. ●

SOCIETIES

BRITISH HERPETOLOGICAL SOCIETY MEETINGS 1987

Meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1, and generally start at 7:00 pm. For further details and membership, please write to BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, England. As always, *SSAR members* and other North American herpetologists visiting or passing through London *are most welcome.*

February 24. Dr C.J. McCarthy: Sea snakes.

March 24. A.G.M. (see separate Agenda), followed by Keith Corbet: 'Biogenetic reserves' and conservation of European herpetofauna.

April 29. Dr T.R. Halliday: Reproductive cycle and life history of newts.

May 28. Education - the link between captive breeding and conservation: the work of the Education Committee. Speakers: Vic Taylor (Chairman); Colin Fitzsimmons; Dr Graham Walters; Peter Curry. Details to be announced later.

June 27. Dr J. Samour: Biomedical survey of the Aldabran giant tortoise population in the Seychelle Is (Indian Ocean). A special Saturday afternoon lecture, starting at 2:30 pm. Joint meeting with the British Chelonia Group.

July 22. Amphibia and reptiles worldwide: Their care and breeding. A discussion organized by the Captive Breeding Committee (Chairman: Simon Townson). Members are encouraged to bring live animals, preserved specimens, amphibian voice recordings and 35 mm slides for display and to illustrate discussions.

September 24. Care and breeding of amphibia and reptiles: an open meeting. Contributions from members - slides, live animals etc. There will be facilities for the sale and exchange of members' private stock.

October 13. Mike Linley: Herpetofauna of New Zealand.

November 18. Dr C.J. Reading: Ecology of the common toad *(Bufo bufo)* with reference to breeding strategies.

Please note that the name of the Society's journal has been changed to *The Herpetological Journal* to reflect better the subject matter of papers published.

MEETINGS

ALL FLORIDA HERP CONFERENCE

The tenth annual All Florida Herpetological Conference and Show will be held April 11-12 at the Florida State Museum, University of Florida, Gainesville, Florida. Registration and program information is available from Rhoda Bryant, Florida State Museum, Museum Road, Gainesville, Florida 32611, USA. (904) 392-1721. ●

ASIH 67th Annual Meeting

The American Society of Ichthyologists and Herpetologists and the American Elasmobranch Society will hold their annual meetings at the New York State Museum, Albany, New York, 21-26 June 1987. The meetings will include symposia, workshops, field trips, contributed-paper and poster sessions, exhibits, social events and business meetings. Symposia and workshops will include: Biology of Unisexual Vertebrates; The Role of Introduced Fishes, Amphibians, and Reptiles in Natural Systems; Reproduction in Tropical

SNAKES: ECOLOGY AND EVOLUTIONARY BIOLOGY

Edited by
Richard A. Seigel, Savannah River Ecology Laboratory,
Joseph T. Collins, Museum of Natural History, University of Kansas,
Susan S. Novak, Savannah River Ecology Laboratory

In ecological and evolutionary research, snakes occupy a unique niche. Studies of their adaptations and life histories have broad implications for the most basic questions of biology. Although their secretive and sometimes venomous nature has discouraged research, recent methodological and conceptual breakthroughs have led to a large but unreviewed literature available only to specialists.

Snakes fills the need for an up-to-date text/reference on the growing field of snake ecology and evolutionary biology. Here, in one volume, is an extensive review of the biology of these fascinating reptiles, including such topics as zoogeography, fossil history, systematics, foraging, and reproduction. With contributions from many leading herpetologists, this work is divided into sections on *Systematics and Morphology, Techniques,* and *Life History and Ecology.* Each section summarizes what is known about these major fields of snake biology and synthesizes the primary literature, both for the experienced investigator overwhelmed by the mass of citations available and for the student just starting to study snakes.

Snakes will well serve the needs of those actively involved in research and will stimulate new and innovative herpetological research. The biological community—the experienced researcher, the amateur naturalist, and the beginning student—will find *Snakes* invaluable.

Anurans; and Skeletal Anatomy of Cyprinid Fishes.

All contributed-paper and poster sessions, symposia and workshops will be held at the State Museum in the Cultural Education Center of the Empire State Plaza. Housing will be available at nearby Siena College or at several hotels in Albany. Planned social activities will be held at various locations in the greater Albany area. Since Albany is at the eastern terminus of the Erie Canal it is readily accessible from all parts of the Continent; more modern forms of transport can also be used. All people interested in fishes, amphibians and reptiles are invited to attend. Additional information can be obtained from Robert A. Daniels, New York State Museum, CEC 3132, Albany, New York 12230, USA. ●

FIRST SOUTH AMERICAN CONGRESS OF HERPETOLOGY

The first South American Congress of Herpetology is scheduled for 21-24 September 1987 in Tucumàn, Argentina, under the sponsorship of the Asociación Herpetologica Argentina - PNHERP CONICET. Sessions will include invited presentations, contributed papers, and workshops. Contributed papers (including abstracts in Spanish) will be accepted until 30 June 1987. For registration materials and further information, write to Dr. Raymond F. Laurent, Asociación Herpetologica Argentina - PRHERP CONICET, Miguel Lillo 251, 4000 San Miguel de Tucumàn, Argentina. ●

UK JOINT HERPETOLOGICAL SOCIETY SYMPOSIUM

The first UK Joint Herpetological Society Symposium was held in the lecture theatre of the London Zoological Society, Regent's Park, London on 14 September 1986. It was attended by one-hundred-and-seventy delegates.

Papers presented were: Breeding *Bombina maxima* (Bob Bray); Frogs of Sarawak (Chris Mattison); Reptiles and amphibians of Gregory National Park, N.W. Territories, Australia (Paul Edgar); Veterinary aspects of reptile husbandry (Rob Harper); Reproduction of Hermann's tortoise and the problem of their disposal (Don Reid); Environmental lighting (Dave Blatchford); Amphibian Husbandry (Mike Linley); and Captive breeding of tropical and temperate reptiles in Pennsylvania (John Brunner).

This highly successful event was organized by Jon Coote. The proceedings will be published in the near future.

FEATURES

NOTES ON THE FEEDING BEHAVIOR OF A JUVENILE MUD TURTLE *Kinosternon scorpioides*

Kinosternon scorpioides (Linnaeus, 1766) ranges from Mèxico to Argentina (Pritchard 1979), where it is often found in murky bodies of water (Freiberg 1972; Acuña et al. 1983). Despite its wide distribution, little is known of its natural history (Pritchard 1979). Excluding parasitological and systematic papers, most information about the species can be found in Teska (1976), Acuña et al. (1983), Pritchard and Trebbau (1984) and papers cited therein.

We know of no reports about the hatchling and early juvenile stages, which are known only from uncaptioned drawings in Gunther (1902). A presumed hatchling is recorded from Cayenne (Pritchard and Trebbau 1984). The following notes regard behavior in captivity of a single individual of *K. s. cruentatum*, and are published because our many attempts to obtain further specimens failed.

At the beginning of the 1983 dry season, two *K. scorpioides* were hand-collected while they were motionless in a bed of mud and leaf trash in Central Costa Rica (San Pedro de Pavas, San José Province). Adults of the species have been reported at this pool (Acuña et al. 1983). At capture, the specimens measured: length of plastron 3.8 and 4.9 cm; carapace 5.0 and 5.2 cm; width of plastron 3.3 and 4.7 cm; carapace 4.8 and 4.8 cm. Their plastral hinges were not functional. One individual died within 20 hours; the other survived approximately 3 months in an opaque aquarium (6 x 7 x 16 cm, with 336 cm^3 of water and a small stone as dry section). The observations reported here are based on the longest-surviving turtle. Both specimens are deposited in the Museum of Zoology of the University of Costa Rica (MZ:X-0012).

FEEDING BEHAVIOR AND FOOD ACCEPTANCE

The turtle approached an object put in the aquarium to ca. 1 cm, with head turned laterally, viewing it with only one eye ("visual examination"). Adult insects and Culicid mosquito larvae that were placed in the water often tried to escape as a result of such approach, generally with success. Biting action was accompanied by strong suction of water, which seemed to help capture small prey (e.g. Culicid larvae). A similar mechanism has been described in taxonomically distant species, e.g. *Chelus fimbriatus* (Pritchard 1984, personal comm.). If the prey was a fast swimmer (e.g. a hemipteran), the turtle normally abandoned the chase after one or two unsuccessful biting attempts. Its general foraging and feeding behaviors were similar to those of temperate Kinosternids (see Mahmoud 1968; Hulse 1974).

We believe that the visual sense of this turtle was of key importance in the location and

Table 1. Food acceptance of a juvenile *Kinosternon scorpioides* turtle

FOOD ITEMS OFFERED	NUMBER OFFERED	NUMBER CONSUMED
Culicid mosquito larvae	697	634
Juvenile *Aplexa fuliginea* snails (length about 1 mm)	79	0
Live flies *	28	26
Adult *A. fuliginea* snails (length about 1 cm)	21	15
Aquatic oligoquete worms (length about 1 cm)	9	3
Aquatic oligoquete worms (length about 10 cm)	5	4
Dead Culicid mosquitoes	3	0
A. fuliginea egg capsules	3	0
Water hyacinth *(Eichhornia crassipes)*	3	0
Dead beetles	2	0
Dead ants (length about 3 mm) *	1	0
Cabbage leaves *	1	0
Live spiders *	1	1
TOTAL	853	683 (80%)

* Foods that were not collected in the turtle's habitat, and were offered only for comparative purposes.

recognition of food, as suggested by the following observations. 1. When 34 Culicid larvae were introduced into the aquarium and the aquarium was placed into a light-tight bag for 46 hours, none of the larvae were eaten. However, as soon as the aquarium was exposed to daylight, the turtle started to consume the larvae. The experiment also suggests that the turtle could not locate the larvae by olfactory or tactile stimuli. 2. The turtle approached inorganic dark objects in the aquarium as described above ("visual examination"). 3. By observing suspended silt flow as suggested by Carr (1952), we saw that it rarely sniffed food.

When eating prey that was difficult to swallow, such as large earthworms, the turtle showed rhythmic inflations of the neck, which apparently aided ingestion. Finally, the neck was fully extended and bent upwards until the food was totally swallowed. Undesired food parts were expelled orally with a spurt of water.

Table 1 shows that a wide variety of prey was accepted, including live oligochaete worms, snails, flies, and mosquito larvae. When several of these items were available, the turtle ate the larvae first. Mosquito larvae were immediately recognized as food when first offered, and on one occasion, 148 of them were consumed within 24 hours. The food of adult *K. scorpioides* consists of tadpoles, crustaceans, insects and their larvae, Poeciliid fishes, molluscs, and worms (Fiasson 1945; Acuña et al. 1983).

ACKNOWLEDGMENTS

We thank A. Chacón, R. Acuña, D. C. Robinson, C. H. Ernest and several anonymous reviewers for comments on the manuscript. Our special thanks to P.C.H. Pritchard for a very interesting dialogue on this matter and for his encouragement.

ANTIPREDATOR RESPONSES OF *Rana tigerina* TO A CROW

At 1500 h on 9 January 1984 we observed an Indian Crow *(Corvus splendens)* attack an adult frog *(Rana tigerina)* 90 mm SVL. The observation was made at the Madras Snake Park, Madras, India, where frogs of many species are released into enclosures as food for monitor lizards *(Varanus)*. The crow attacked the frog on the ground and carried it to the stone wall of the lizard pen. The frog emitted a series of mercy screams audible to us at a distance of 5 m. The crow pecked repeatedly at the ventral surface of the frog with the beak closed but did not break the skin of the frog. After a number of pecks the frog righted itself and assumed a defensive posture with the body inflated and the hind limbs extended; this posture was very similar to that reported for other species of *Rana* (Altig 1972; Formanowicz and Brodie 1979; Hinsche 1926).

As the *R. tigerina* assumed the defensive posture the crow pecked it on the dorsal surface of the body several times and finally on the hind leg, flipping the frog onto its dorsum. After being flipped the frog remained immobile. The crow shook its head with the bill open and wiped its open bill on the substrate; this is typical of distasteful responses of other birds to amphibians (e.g. Howard and Brodie 1973; Johnson and Brodie 1975). The crow walked 2 m from the frog then flew to a nearby tree; it returned once to the frog for a few seconds but did not peck it again. The crow then flew away. We observed the frog for an additional 5 min during which it remained motionless on its dorsum. We then retrieved and examined the frog. The skin had not been broken by the pecking of the crow. The frog then righted itself and hopped. We kept the frog for 24 h and it did not appear to be injured in any way.

We observed a crow eating another (longer-legged) *Rana* in an adjacent pen later the same day.

We conclude from these observations that: 1) Crows do attack frogs, and 2) *Rana tigerina* has a skin secretion sufficiently unpalatable to repulse crows. Observations such as this along with carefully designed experiments will allow us to more fully understand the antipredator mechanisms of frogs.

We are grateful to Romulus Whitaker for allowing us to make these observations at the Madras Snake Park and to a Smithsonian Foreign Currency grant supporting our travel.

RANGE PORTRAYAL AND REALITY: "BIAS" OR SCALING PROBLEM?

Recently, Axtell (1983) claimed that most maps of the distribution of the eastern hognose snake, *Heterodon platyrhinos*, were biased in not showing certain fine details of the range. Specifically, he contended that such maps should be drawn with collection localities marked with dots and map outlines drawn with dash lines to accentuate ambiguity (where it exists). Included in the maps he mentioned were those by Wright and Wright (1957), Platt (1969), Conant (1975) and Blem (1981). At the risk of being accused of being a proponent of inaccuracy, I present in this note some arguments that show that these maps are not biased but are constrained by scaling problems.

First, it should be noted that map size restricts the potential degree of accuracy of *H. platyrhinos* maps. For example, Axtell's (1983) map accurately shows the distribution of *H. platyrhinos* along rivers in the high plains of Texas and Oklahoma. If a similar scale had been used by mappers of its total distribution, the resulting maps would be slightly larger than 100 X 100 cm. Obviously, field guides or catalogues of these dimensions are not likely to be useful or produced at reasonable costs. Furthermore, the loss of accuracy that results from the use of smaller maps in no way satisfies the definition of "bias" (i.e., introduction of systematic error).

Secondly, my original map (Blem 1981) included all major tributaries and clearly showed the riparian nature of the distribution of *H. platyrhinos*. In a logical attempt to conserve space and expense, editors of the ASIH catalogue reduced the size of the map and omitted the drainages when the map was redrawn. However, the account clearly states that the species "extends westward along river valleys." Platt's (1969) description of this distribution is similar. Although Conant (1975) and Wright and Wright (1957) do not make this point clear, their maps do achieve their purpose (i.e., to show the general distribution of this species).

Thirdly, while locality dots are excellent features in maps covering relatively small areas, the dots themselves create confusion on large scale maps. On my map of the U. S. distribution of *H. platyrhinos* the dots (which are very small) cover an area equal to approximately 40 km in width. Axtell's range expansion (76 km) would scarcely be visible on this scale and its importance would be minimized. If one attempts to draw a "dot map" with dots of about 1 mm in diameter and a scale of 1 mm = 1 km, a map of the distribution of *H. platyrhinos* would be about 27 cm X 24 cm and a U. S. map would be 43 cm x 29 cm. Such maps would be unwieldy, but smaller scales would obscure drainages (many major tributaries are less than 1 km wide) and even then range expansions of less than 20 km would be difficult to map.

Finally, I agree with Axtell that knowledge of uninhabited areas within outlined ranges on large scale maps is important. In fact, this problem is as significant for the hognose snake as the western edge portrayal. For example, there are huge areas in states like Ohio (Blem 1972) that seem devoid of hognose snakes. However, on the scale that field guide maps are drawn, one cannot expect to show these details. Also, since all ranges are subject to change and are seldom certain, map boundaries would always be drawn in dash lines.

In summary, I do not agree that major maps of *H. platyrhinos* are biased or greatly inaccurate. For their purpose they are perfectly appropriate. More detailed distributional analyses are the province of state publications or monographs, or, if sufficient interest exists, large encyclopedic atlases.

MORE ACCURATE RANGE PORTRAYAL, EVEN ON SMALLER MAPS? AXTELL'S ANSWER TO BLEM'S PROTESTATIONS

First, I want to stress that I would be the last individual to argue that map portrayal is anything more than a gross representation of reality, but the closer we can come to some ideal representation the more informative our maps become.

Second, a brief statement to describe how I viewed the 1983 manuscript as it was being prepared, since my perception at that time differed considerably from the interpretation Blem has given it (see above). I was using the map of *H. platyrhinos* as an example, a vehicle if you will, to express some of my longstanding concerns about how we portray organismal distributions on maps. My basic argument was for an approach that adds physical and/or environmental information as well as individual dot records during map preparation. With these additions we might begin to understand and appreciate how distributions conform to landforms, soils, geology, vegetation or any other environmental factor that may be of interest.

Third, I'll now address Blem's two specific criticisms, i.e., my use of the word *bias* and what I'll call the *size problem* (Blem calls it *scaling*), especially with regard to small (i.e. catalogue and fieldbook-sized) maps. In my 1982 publication I asserted that all previous *H. platyrhinos* maps had presented a biased portrayal of reality because the method of mapping over-generalized information known to the mappers. At the time I didn't consider this a direct criticism of any of the earlier mappers (although now I can see that it certainly could have been taken that way) because they had simply practiced conventional mapping techniques that had been in use for decades. However, I was criticizing a mapping method that I believed had outlived its usefulness. Perhaps I should have used the term *generalized portrayal* instead of *biased portrayal*, but with the term bias I wanted to emphasize the way I believe our maps affect a reader's perceptions of distribution patterns. Their interpretation of these patterns almost certainly is influenced (or biased) by such maps, and if the maps are generalized then their interpretations probably will also be generalized. The question I ask is: Do we wish to continue perpetuating such inaccuracies in the name of simplicity and easy comprehension, or should we try to do something about it? I believe I've answered that question, at least for myself. Although I did not directly address the small map problem in my 1983 publication, it was partially considered in the comparative maps shown at the bottom of Fig. 1. Those maps were included to illustrate how different two mapping approaches could be when compared. I used no locality dots on the maps, which were prepared to match the fieldbooks style. While Blem's (see above) interpretation makes it seem that I was advocating dot records on **all** maps, my sentence on page 193 ["2) Actual locality (dot) maps **should** be prepared **whenever possible** so that investigators can interpret such range information independently" (bold face not in original)] clearly indicates that I was not that dogmatic. I agree that one does run into scaling problems when drawing small maps. Obviously you can't get as much on a postage stamp sized map as on a 100 x 100 cm map, but we all

know that small maps are usually drawn larger first and then reduced for publication. Not a great deal of clarity is lost during this process because everything is reduced proportionately. And if a line or a dot can be drawn on paper, it can still be clearly seen even after considerable reduction. As an example of this, I first enlarged Conant's (1975) range map of *H. platyrhinos* 308 per cent on a Xerox copier; then I redrew it (using various dot map sources, i.e., Anderson 1965; Blem 1981; Conant 1951, 1975; Platt 1969; Smith 1961; Vogt 1981; and Webb 1977) and finally I reduced the map photographically back to Conant's original publication size. The result along with Conant's original map, is presented below as Fig. 1. This map shows many peripheral records (except for Texas) as isolated dots. It draws attention to certain problematic regions in several states (i.e. Oklahoma, Missouri, Iowa, Illinois, Indiana, Michigan, Ohio, and West Virginia) where further investigation may be needed to establish more accurate range boundaries (and possibly to generate future explanations for those patterns so they can later be tested). Question marks appear in South Carolina, Kentucky, Tennessee, and Louisiana because Blem (1981) portrayed few records for any of these states (i.e. 4, 6, 4 and 4 respectively). As a reader, I am not sure whether these were "token" localities to fill in map space, or whether there are distributional peculiarities in these states that need closer examination.

We also need to be more cognizant of local distributions in states reportedly having pandemic occurrence of particular organisms. For example, Mount's (1975) dot map of *H. platyrhinos* range in Alabama suggests that there may be many areas in that state where the eastern hognose does **not** occur, yet his caption for Fig. 216 states that "the species is believed to occur statewide, or essentially so." By including such a statement, Mount may have unintentionally reduced interest in *Heterodon* distribution in Alabama by a significant amount, for if most investigators believe that this snake has a statewide distribution, then why try to report a new county record, or why try to find out why *H. platyrhinos* does or does not occur in some particular area?

In closing, I'm still convinced that we can make both large and small maps better; that we can with proper map presentation, encourage the accumulation of new and more enlightening geographic information, and with this information be better able to find why animals are where they are and possibly even how they came to be there.

MORE ACCURATE RANGE PORTRAYAL: CONCLUSIONS

Since Axtell has recanted his use of the term "bias," our debate seems to boil down to subjective evaluations, i.e., do "tiny dots" maps improve upon traditional line maps, and do these maps accurately show fine detail, particularly at the edge of the range.

As a student of "edge of the range" phenomena, I especially appreciate Axtell's efforts to map range limits precisely. However, dots on small maps do not improve upon an accurately drawn line. I feel that Axtell's redrawn version of Conant's (1975) hognose snake map supports this observation. Dot maps drawn at the appropriate scale are a distinct improvement; "tiny dot maps" only give the impression of accuracy.

Dot maps present an additional problem. At what "dot density" do we stop drawing dots and simply indicate that the species may occur throughout the range? Nearly every species has disjunct populations at the edge of the range; drawing dots for all of these would require more effort than field guides warrant. In some species the distances between many locality records are greater than Axtell's hognose snake range expansion. Do we draw all of these records as dots and redraw the maps every few years as records accumulate? It seems to me that such maps should be the goal of more localized studies or perhaps could be compiled by a committee of distributional herpetologists selected from national societies.

In conclusion, I too encourage accuracy in mapping and accuracy in distributional data where it is appropriate. We definitely have much to learn about the biology of range limits. Let's just not get carried away with adding dots to maps.

SOME RECENT INTRODUCTIONS OF REPTILES IN THE CAYMAN ISLANDS, WEST INDIES

Minton and Minton (1984. SSAR Herp. Review 15(3):77) reported the presence of *Anolis sagrei* in the vicinity of George Town, Grand Cayman, Cayman Islands, where it outnumbered the endemic *Anolis conspersus* "in about a 2 to 1 ratio."

In early 1986 we noted the continued presence of *Anolis sagrei* in George Town and South Sound areas, and documented introductions of *Elaphe guttata guttata* on Grand Cayman and *Anolis maynardi* on Cayman Brac. It is our belief that both *Anolis sagrei* and *Elaphe guttata* arrived recently in the Cayman Islands from south Florida with nursery stock used for landscaping.

Elaphe guttata guttata (Corn Snake). GRAND CAYMAN: Golf Course, Brittania Condominiums, 3.5 km N of Harbor, George Town 11 September 1985. University of Florida (UF 63455-63456). The initial specimen was killed by workmen as they unloaded exotic shrubbery and trees imported by ship to Grand Cayman from a nursery located in the Miami area. These workmen also reported seeing other individuals at the same time, but were unable to kill them before they escaped. In January 1986, the second specimen was caught by a workman at the condominium.

Anolis maynardi. CAYMAN BRAC: 2.4 km SW of Stake Bay, "The Creek" settlement. 31 Jan 1986. (UF 63457). Other specimens were seen on trees adjacent to the Cayman Brac Airport and 1 km E of airport. People who live between the Airport and The Creek know these green lizards, and reported often seeing them on trees in their yards. No specimens were seen elsewhere on the island. Mrs. Cynthia Scott, a lifelong resident of the Brac and avid naturalist, remembered that these lizards first appeared in her yard in the mid-1970s. *Anolis maynardi* is endemic to Little Cayman and was probably accidentally transported to the Brac on commodities shipped across the 11 km wide seaway that separates the two islands.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

CAPTIVE *Phrynosoma solare* RAISED WITHOUT ANTS OR HIBERNATION

Horned lizards (genus *Phrynosoma*) are dietary specialists on various genera of ants (Hotton 1955; Pianka and Parker 1975; Whitford and Bryant 1979; Rissing 1981; Munger 1984). Their poor feeding and survival in captivity has long been attributed to lack of, or insufficient, ants in the diet (Wynne 1981; Switak 1984); it was presumed that ants contain a nutrient not available in other food items offered. Recently some workers have achieved success at breeding *Phrynosoma* in captivity (Baur 1973, 1979a, 1979b, 1984; Montanucci 1983) by feeding ants and other insects, utilizing ultraviolet or natural light, and hibernating animals in winter. Mayhew (1965) reported one species, *P. m'calli*, to be an "obligatory hibernator." This report on *P. solare* demonstrates that horned lizards can be raised to two years of age (adult) without ants in the diet, suggesting that factors other than ants were responsible for earlier failures and current successes, and notes that hibernation may not be "obligatory," at least in young animals of this species. Nevertheless, ants in the diet and/or annual hibernation may be beneficial to some captive horned lizards.

METHODS

An adult female *P. solare* (114 mm snout-vent length, 81.9 g) was collected near Huerfano Butte, Santa Rita Mountains, Pima Co., Arizona, on 2 July 1983, and was maintained in an aquarium (see below). Thirty-two eggs were laid underground sometime between 26-30 July 1983 and were removed and placed on damp vermiculite in a plastic bag (method of Zweifel 1961) on 7 August 1983 for incubation. Embryos were removed from the clutch for study throughout incubation and ten live hatchlings emerged 15-18 September 1983, of which eight were raised.

Hatchlings were fed *Drosophila* sp., hatchling crickets *(Acheta domesticus)*, and tiny mealworms (*Tenebrio* sp.); the latter two items were dusted with Theralin ® (Lambert-Kay Division, Carter Wallace Inc., Cranbury, NJ), a vitamin-mineral powder containing Vitamin D_3. As the hatchling lizards grew in size, fruit flies were discontinued and larger-sized crickets and mealworms were used. The rear legs of larger crickets were removed to facilitate prey capture. At no point were ants fed to these lizards.

Lizards were sprayed several times a week with a mist of water for drinking. Care was taken to wet the head thoroughly and to continue the misting until an individual learned to drink in this fashion. Spraying continued throughout the period during which the lizard's jaw-motion indicated ingestion of water.

The hatchlings were maintained, as was their mother, in an open-topped, glass-walled aquarium (25x50x30 cm high) in a windowless, air-conditioned/heated building at the University of Arizona, Tucson. Lighting was provided by two 122 cm long fluorescent bulbs, one 40W Vita-Lite® (Duro-lite Lamps, Inc., Fair Lawn, NJ) and one F40CW Lifeline Sylvania® (NAP Consumer Electronics, Knoxville, TN), suspended crosswise above the aquarium, 50 cm from the 3-5 cm-deep sand substratum. A Sylvania 250W heat lamp was placed 45 cm above the substratum at one end of the cage. After the loss of three hatchlings (possibly due to metabolic bone disease) by November, 1983, the Vita-Lite was combined instead with a Sylvania 350 40W Blacklight. Daylength was maintained at 10 h until 21 May 1985, when the aquarium and the one remaining lizard were moved to Portal, Arizona, where, due to the presence of windows, daylength varied with natural lighting. Color photographs (Kodachrome 25), mass, and snout-vent length (SVL) were periodically taken of individual lizards. X-ray photography was used to examine the longest surviving lizard for evidence of metabolic bone disease.

RESULTS AND DISCUSSION

The five lizards remaining after November 1983 continued to feed and grow throughout the winter until the colony was infected by an eye/mouth infection in the spring. One lizard died 10 May 1984, after a period of not feeding due to a mouth infection. Two others, in poor condition and losing weight due to eye infections, were sacrificed 17 June 1984 in an attempt to arrest spread of the disease. On 29 May 1984 the infection had been diagnosed as *Klebsiella oxytoca* and *K. ozonae*. The snout-vent lengths of these three, nearly adult-sized (Howard 1974) lizards, were 64, 74, and 79 mm. The remaining two lizards continued to feed and grow, attaining 89 mm SVL (49.1 g) and 97 mm SVL (73.7 g) by 6 December 1984 and 91 mm SVL (43.3 g) and 104 mm SVL (93.2 g) by 3 May 1985. The largest individual, a female, at this point outweighed, in less than two years, the gravid female (mother) at time of capture. The smaller of these two lizards was sacrificed on 13 May 1985 due to recurrence of the eye infection and weight loss.

Although a small male was placed in the cage with the remaining female during part of the summer, apparently she did not breed. She stopped feeding in late summer, perhaps in response to daylength or temperature changes at her new location and died 22 September 1985 (110 mm SVL), two years after hatching. Autopsy revealed large fat bodies and 25-30 oviducal unshelled eggs; many of these were bloody and one had been passed prior to death.

Throughout their lives in this study, five captive, growing lizards passed through one winter, and two of these passed through two winters, without cessation of feeding or reduced activity, indicating that younger animals of this species, at least, are not "obligate hibernators." Perhaps there are physiological differences between individuals and/or between species of horned lizards in terms of hibernation.

As mentioned above, ants were specifically excluded from the diet. In spite of this, lizards

fed and grew rapidly. The only problems noted with the prey used as food resulted from prey size and escape behavior. Horned lizards generally use their tongues in a manner similar to toads (Sherbrooke 1981) to retrieve and ingest ants. Potential food items that are either not active enough to approach the lizards (mealworms), too heavy for tongue-mediated lifting into the mouth (large mealworms, large crickets), or competent at rapid escape (crickets with intact hindlegs), frequently escape ingestion. The lizards tire of failing to catch them and learn to ignore their presence. Therefore, the size and mobility of food items is critical in maintaining healthy horned lizards in captivity.

Because many ants bite or sting them, horned lizards tend to panic if surrounded by numerous prey items. They should be fed ants in small numbers (Knowlton 1946; Baur 1973; Montanucci 1983). An observation on ten captive *P. modestum* suggests that small crawling crickets are "perceived" by horned lizards as not only appropriate food items, but as ants. This occurred when a number of lizards in an aquarium retreated, walking backwards while continuing to feed, as they would with ants (they do not "like" ants to get behind them), before a front of advancing hatchling crickets that had been dumped in large numbers into one end of the tank.

Earlier failures at captive raising of horned lizards were probably due to insufficient attention being given to prey size and mobility, method of providing water, thermoregulatory needs, Vitamin D_3 and sufficient amounts of proper minerals in the diet, and ultraviolet radiation, rather than to lack of ants in the diet. Attention to these requirements has proved highly successful in establishing laboratory colonies of *Cnemidophorus* (Cole and Townsend 1977; Townsend 1979; Townsend and Cole 1985) and *Phrynosoma* (Montanucci 1983). The loss of the three youngest hatchlings of *P. solare* in this study is tentatively attributed to insufficient ultraviolet radiation for proper calcium metabolism. In order to verify healthy calcium metabolism in the two-year old *P. solare*, it was x-ray photographed on 18 July 1985 (Fig. 1). Limb and other bones lack evidence of metabolic bone disease (compare with photograph in Townsend and Cole 1985).

Captive *P. solare* in this study were seen to extrude their tongue and ingest small pebbles, in a manner similar to feeding behavior. Pebbles were later passed in the scats. The length of time they remain in the stomach (Fig. 1) or other parts of the digestive tract is not known. Other horned lizards, *P. cornutum* and *P. modestum* have also been observed, during extensive behavioral observations in natural habitats, to ingest pebbles and soil which turn up in their scats (pers. obs.). Sand (Loennberg in Milne and Milne 1950) and stones (Tanner and Krogh 1973) have been reported previously, but no significance has been attributed to them other than incidental objects inadvertently ingested. My observations lead me to suggest that horned lizards deliberately eat these substratum objects. Four possibilities for such behavior come to mind: pebbles/sand/soil 1) are used to grind insects in the stomach, 2) physically remove or control digestive tract nematodes,

Figure 1. X-ray of *Phrynosoma solare* on 18 July 1985, nearly two years after hatching in captivity. Note lack of metabolic bone disease (limb bones all intact and joints not degenerating) and a group of pebbles in the stomach (dark spots at posterior right).

3) serve as a source of minerals in the diet, or 4) are mistaken for immobile prey.

Townsend and Cole (1985) report hatchling *Cnemidophorus* eating unwashed, ocean beach sand (fragments of invertebrate shells — not quartz sand; pers. comm. Townsend and Cole). Since lizards in this study continuously ingested pebbles despite lacking intestinal nematodes, I currently favor the insect grinding and mineral hypotheses; these ideas need study. Horned lizards have well-developed taste buds (Schwenk 1985) that could play a role in selecting mineral-particles for ingestion.

Many species of horned lizards harbor large numbers of intestinal nematodes, reported as *Skrjabinoptera phrynosoma* in *P. cornutum*, and probably the same species occurs in *P. solare* (Lee 1955, 1957). Lee (1957) establishec that ants are the intermediate hosts in the parasite cycle, requiring ingestion by horned lizards. Consistent with this observation, and in contrast to the condition of their wild-collected mother, autopsy of the five largest *P. solare* raised in captivity without ants revealed no nematodes in the digestive tracts.

ACKNOWLEDGMENTS

I thank W. H. Birkby for taking the x-ray, J. T. Bagnara for laboratory facilities and crickets, J. A. Cole for assistance in the field, C. J. Cole and C. R. Townsend for advice on captive raising of lizards and comments on the manuscript, J. L. Jarchow for identification of *Klebsiella*, F. W. Morrisett for intermittent care of live lizards and for printing Fig. 1, R. R. Montanucci and B. E. Baur for useful suggestions that improved the paper, and the Arizona Game and Fish Department for scientific collecting permits.

Announcing the Reprint of a Classic on the Herpetology of Mexico and Central America

BIOLOGIA CENTRALI-AMERICANA:

Reptilia and Batrachia by Albert Günther

•

With New Introductions by Hobart M. Smith and A. E. Gunther

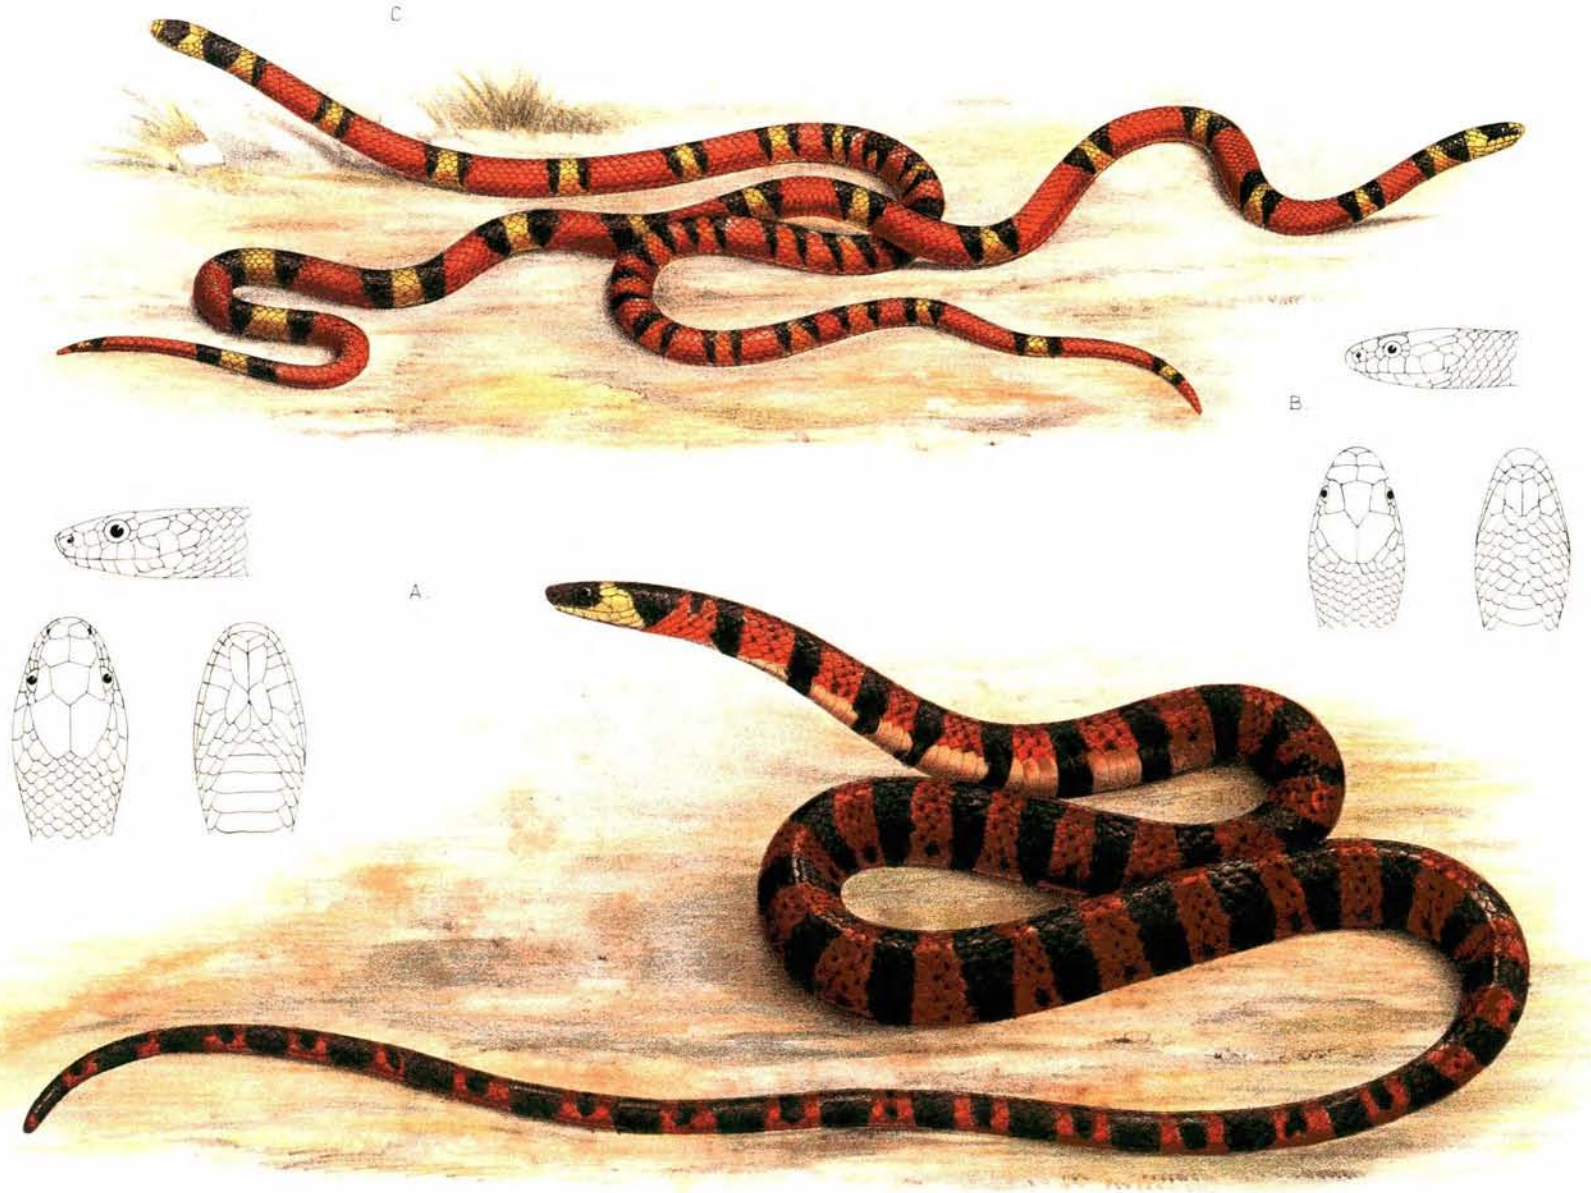
About 500 pages, 76 plates (12 in full color); format 8.5 x 11 inches (21.5 x 28 cm), clothbound. To be published September 1987.

The series *Biologia Centrali-Americana*, published in London in 67 volumes over the period 1879 to 1915, is the most comprehensive summary ever issued covering the botany and zoology of Middle America. The volume on amphibians and reptiles was entrusted to Albert Günther of the British Museum (Nat. Hist.) who was one of the leading herpetologists of his era. As for the entire *Biologia* series, the geographic coverage extends from the USA-Mexican border through Panama including the adjacent islands. This region contains one of the largest and most diverse herpetofaunas in the world. The volume covers 695 species, of which 58 are described as new in addition to three new genera, and it has been out-of-print and unavailable for decades. Because of this scarcity, copies have brought as much as $1000 recently on the second-hand market.

A major reason for the continuing value and importance of this book today is the series of 76 full-page plates which depict 138 species in 435 individual figures. These detailed plates, drawn by some of the most distinguished natural history artists, are among the finest likenesses, both scientifically and aesthetically, of amphibians and reptiles ever published (see sample plate on reverse side). Twelve of these plates are colored in the original and all are reproduced in full color in this reprint. Because of the outstanding beauty of these color plates -- which include turtles (3 plates), lizards (2), snakes (5), and frogs (2) -- 400 separate sets are being printed but only 250 sets are being offered for sale.

Professor Smith provides an introduction that will greatly increase the book's utility. This includes information about the author and editors, details about the collectors and collections, and an extensive table equating Günther's species names to modern nomenclature. Doctor Gunther, the author's grandson, has written an in-depth biography of Albert Gunther with a complete listing of his 200 herpetological publications.

This reprint is being issued to commemorate the Society's 1987 meeting in Veracruz, Mexico, its first outside the USA. Printing costs are partly underwritten by a Patron and the Friends of the Society, allowing for special low prepublication prices.



PRICES AND ORDERING INSTRUCTIONS.

Copies of the book and sets of plates can be obtained from the Publications Secretary, Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR"; receipt sent on request only. *Prices include shipping charges* (book rate) within USA; all overseas orders will be billed only for the *additional* postage. Publications sent at customer's risk; however, packages can be insured at your cost. Overseas customers must make payment in USA funds, by International Money Order, or by MasterCard or VISA (in which case account number and expiration date must be provided).

- **CLOTHBOUND BOOK (ISBN 0-916984-17-6):**
  - Prepublication price to SSAR members if ordered before 1 September 1987.....$28
  - Price to Institutions, Non-members, and to all purchasers after 1 September 1987.....$50
- **SET OF 12 COLOR PLATES (wrapped in protective plastic cover):**
  - Prepublication price to SSAR members if ordered before 1 September 1987.....$10
  - Price to Institutions, Non-members, and to all purchasers after 1 September 1987.....$18

The Society publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology* (monographs), and *Catalogue of American Amphibians and Reptiles*. Pricelists are available from Dr. Taylor who can also supply information about Society membership on request.

TECHNIQUES

A METHOD FOR ESTIMATING RESIDUAL YOLK MASS IN HATCHLING CROCODILIANS

During the later stages of embryonic development, birds and reptiles typically internalise the vitelline sac, which contains a supply of yolk (Romanoff 1960; Ewert 1979; Ferguson 1985). The residual yolk (Romanoff 1960) thus formed represents a significant source of nutrition for the immediate post-hatching period. The selective advantages of residual yolk masses have been speculated upon by a number of authors (for example Ferguson and Joanen 1982, 1983 and Packard et al. 1981). To measure the amount of residual yolk accurately, hatchlings need to be sacrificed, but this precludes their use in further experiments. Furthermore, sacrificing large numbers of crocodilian hatchlings cannot sometimes be justified on conservation grounds (Gans and Pooley 1976). We derived a simple method for predicting residual yolk mass from abdomen dimensions in *Crocodylus johnstoni,* which has allowed us to use residual yolk mass as a variable in experiments which examine the relationship between incubation environment and post-hatchling growth and survivorship. The method should be applicable to other crocodilians and perhaps lacertilians.

Thirty-seven *C. johnstoni* hatchlings from eggs incubated at different temperatures were sacrificed on the day they hatched. Prior to administering a lethal overdose of Nembutal (Sodium pentabarbitone), each hatchling was laid on its back and had the maximum width of the abdomen from right to left (A in centimetres) and the maximum width of the umbilical scar (U in centimetres) measured with calipers. Total hatchling mass (residual yolk mass plus hatchling mass), head length, snout-vent length and total length were also measured (Table 1). After death, the residual yolk was removed and weighed (Table 1).

Table 1. Means and variances for seven parameters measured on a sample of 37 *C. johnstoni* hatchlings. Lengths and widths given in centimetres, masses in grams.

VARIABLE	MEAN	VARIANCE
Head length	3.72	0.035
Snout-vent length	11.72	0.265
Total length	25.22	1.563
Total mass	47.20	36.522
Residual yolk mass	10.03	15.579
Abdomen width	3.55	0.131
Yolk scar width	0.77	0.094

Least squares multiple regression analysis (Genstat) was used to predict residual yolk mass (in grams) from combinations of the measurements taken. Both A and U accounted for significant amounts of the total variance in residual yolk mass (83%, $F_{1,33} = 353.57$, $P < 0.001$, and 7% $F_{1,33} = 32.23$, $P < 0.001$ respectively). Additionally, various transformations of the parameters measured were computed (square root, square, natural logarithm) and then tested in the regression in an attempt to improve the overall fit. The square transformation used was computed as the square of an individual's deviation from the sample mean for a particular parameter. This allows a statistically sound method to model a parabolic relationship. Of those tested, only the square of the deviation of each individual hatchling's mass from the mean mass of the sample 47.2 g (WTSQ) accounted for a significant amount of the total variance (2%, $F_{1,33} = 8.38$, $0.01 > P > 0.001$).

The model which explained most variation (92%) in residual yolk mass was:

ln(residual yolk) = -1.055 + 0.843A + 0.459U - 0.0019WTSQ

The natural logarithmic transformation generates an asymmetrical error equivalent to approximately $\pm$ 1 g. For an independent sample of animals (n = 8), which died on the day of hatching or were sacrificed as part of another experiment, prediction errors ranged from 0.0 g (0%) to 1.8 g (19%), and averaged -0.1 $\pm$ 1.1 g (SD).

YOU *CAN* SET DRIFT FENCES IN THE CANOPY!

Quantitative and qualitative methods exist for sampling the terrestrial herpetofauna in tropical rainforests. These include searching leaf litter in the buttresses of trees (Inger 1980), forest litter plots (Scott 1976, 1982), and setting drift fences with pit and funnel traps (Vogt and Hine 1982). However, no one has developed a technique for systematically sampling herpetofauna in the canopies of tropical rainforests. A large percentage of the tropical herpetofauna is arboreal and many "rare" species may be so only because they are rarely encountered when sampling forest floors.

When discussing these problems with Dr. George Zug in December 1980 he could think of no solutions either, but replied: "You can't set drift fences in the canopy, Dick!" In 1981 after moving to Estación de Biología Tropical "Los Tuxtlas" in the evergreen rainforest of southern Veracruz, Mexico, this problem became a reality.

After several abortive attempts, a convenient and inexpensive design (Fig. 1) was developed which catches reptiles and amphibians systematically at different strata of the forest canopy. The main feature is a system of four pulleys, a pair of which is attached to the two highest parallel branches 15 m apart on two trees. A 1 cm diameter nylon rope is threaded through each of the pulleys. Attached at various distances on the rope are "walkways" made of plastic window screening. The 90 cm-wide screening is cut in 15 m lengths. Galvanized wire is then threaded along the entire length on both edges of the screening and a length inserted crosswise at 1 m intervals to give support and maintain the shape of the "walkway." A 1 m length of 5 mm steel rod is tied at each end of the screening

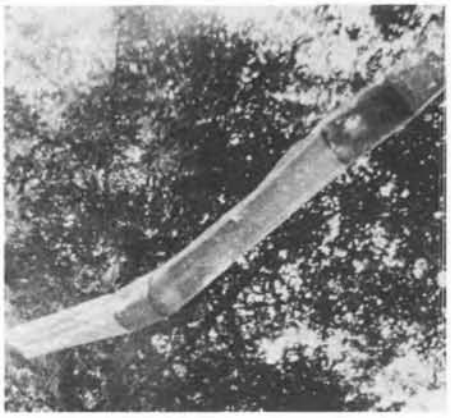

Figure 1. Aerial drift fence set at 15 m. Note the two funnel traps and the guide line extending from the left trap.

to maintain a flat entrance onto the "walkway." Two funnel traps (1 m x 0.8 m) constructed of 8 x 8 mm galvanized wire mesh are sewn onto the walkway with galvanized wire at 5 m intervals. The mouths of the funnel traps take up the entire width of the walkway so that any animal moving along the walkway is directed into the trap. A guide line of 8 mm nylon cord is attached to both sides of each funnel trap so that when the walkway is hoisted to its desired height these ropes can be pulled tight and tied to trees or rocks to prevent it from inverting during winds and rains.

Walkways have been successfully used at three different levels on the same set of ropes: 3 m, 10 m, and 15 m. The 1 m level can be set without hanging it on ropes. The advantage of the pulley system is that once the pulleys are installed the traps can be easily checked at regular intervals with little effort. It is easiest to check the traps by lowering both ends simultaneously. This technique requires a site where the walkway will abut as many trees and branches as possible yet be sufficiently open to raise the walkways to different heights. This system is not efficient for short term use, but is well suited for long term studies where the traps can be set for long periods and checked at intervals of two to five days depending on the density of the herpetofauna.

During the initial testing of the "walkways" snakes (*Leptodeira annulata, Leptophis mexicana, Oxybelis aenas*), lizards (*Anolis humilis, Corytophanes hernandezi, Sceloporus variabilis, Iguana iguana, Basiliscus vittatus*), anurans (*Smilisca baudini, S. cyanosticta*) and salamanders (*Bolitoglossa platydactyla*) were captured in the traps at various levels. To date, no long term and intensive use has been carried out due to time and labor constraints. However, I plan to use these walkways in conjunction with terrestrial drift fences to sample the herpetofauna at all strata of the rainforest.

ACKNOWLEDGMENTS

The development of this technique would not have been possible without the assistance of "los monos de arboles" Rodolfo Dirzo, Santiago Sinaca, and Guillermo Ibarra. The ground crew of Marcelo Paxtian Sinaca and Gonzalo Perèz Higareda was equally important for the success in placement of the traps.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (e.g., Reproduction, Coloration, Morphology, etc.). Figures are permissable to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *breiefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles whereever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, USA.

ANURA

BUFO MELANOSTICTUS (Asian Common Toad). **DENSITY.** This species is the most abundant amphibian in Guangdong Province, China (Pan, Liu, and Qian 1985. Acta Herp. Sinica 4(3):200-208). It is ranked among the six most economically important anurans in Guangdong by Su (1985. Acta Herp. Sinica 4(4):313-319) because of its role in insect predation. No population density estimates have been published. We conducted a mark-recapture study at the Mangrove Protection Station headquarters, Dong Zhai Kong, Kingsan County, Hainan Dao, Guangdong, 15-23 April, 1986. Data were analyzed by the multiple catch method of Tanner (1978. Guide to the study of animal populations, Univ. Tennessee Press, Knoxville: 186 pp.). We used average travel distance, 21 m, to add an edge to our plot and calculated 80 individuals per hectare with 95% confidence limits 56-153. The population was 82% females measuring 75-107 mm SVL ($\bar{X}$ = 90). Males measured 69-80 mm SVL ($\bar{X}$ = 74). No breeding was observed during our study. The habitat was edificarian, ornamental garden and agricultural and, about 4 m above sea level. Our work was supported by The Conservation Agency and Earthwatch, The Center for Field Research.

Submitted by **JAMES D. LAZELL,** The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA, and **LIAO WEI-PING,** Guangdong Institute of Entomology, Guangzhou, Guangdong, Peoples' Republic of China. ●

CAUDATA

AMBYSTOMA MACULATUM (Spotted salamander). **REPRODUCTION.** The gelatinous matrix surrounding the egg clutches of some anurans has thermal properties (Hassinger 1970. Herpetologica 26:49-51; Savage 1970. Brit. J. Herpetology. 3:57-66; Seale 1982. Copeia 1982:627-635). Communal egg deposition in early breeding ranid frogs, such as *Rana sylvatica* and *R. temporaria,* magnifies thermal buffering by insulating eggs against cold water. Lykens and Forester (1986. Herp. Review 17:45) suggested that communal egg deposition might also provide an advantage in reducing dessication in egg masses stranded by receding pond waters. I report herein similar properties associated with the egg masses of the salamander *Ambystoma maculatum,* and an instance of aggregative egg deposition in this species.

I have twice observed stranding of egg masses of *A. maculatum* at a vernal-autumnal kettle pond (maximum surface dimensions 30 X 20 m, maximum depth 1.5 m) located in Culvers Gap, Sandyston, Sussex Co., New Jersey. This pond is surrounded by mixed deciduous-eastern hemlock woods, which shade the pond vicinity much of the day. On 15 May 1977 ca. 25 individual egg masses were found stranded up to 0.7 m from the

shoreline of the pond. I estimate that some masses had been exposed for at least one week. Each mass contained living embryos and some hatchlings within the mass or on its surface.

On 27 May 1986 at least 80 masses of *A. maculatum* were stranded 0.2 - 4 m from the shoreline. The furthest mass was about 50 cm above the current water level. None of the masses was dried or crusted, although most were no longer as firm as masses in water. Virtually every mass retained living embryos or had hatchlings beside, on, within or underneath it. Hatchlings wriggled vigorously and in rain might have been able to return to the pond over the wet, matted leaves, even if a rising water level did not inundate the masses.

In 1978 I enclosed a nearly permanent pond (surface 25 X 12 m, depth 1.5 m) with a drift fence in the Delaware Water Gap National Recreation Area, Sandyston, Sussex Co., NJ. Seven-hundred-ninety-six *A. maculatum* (362 females) entered the pond. Most egg deposition occurred 10-12 April. Aggregations of 10-80 individual egg masses resulted. Most masses were deposited in shallow water and often on the bottom. Receding water levels stranded some masses for up to 35 days; these developed a dry crust. Eggs in individually deposited masses and the smaller aggregates did not survive this period, but eggs in the inner, protected masses of the four largest aggregates (40-80 masses) survived and hatched after they were once again submerged following heavy rains. Overall, only about a third of the eggs in an estimated 200 stranded masses did not survive this prolonged exposure.

Daytime temperatures within masses in the pond were consistently higher than ambient water temperature by as much as 4.0° C. The relation of the temperatures within stranded masses to ambient air temperatures was variable; temperatures directly beneath stranded masses were 1.7-2.0° C lower than internal mass temperatures.

This report documents properties of egg masses and the hatching of eggs in a terrestrial environment which allowed survival despite fluctuating pond levels. These properties may be particularly important for the eggs of *A. maculatum* in which embryonic development may exceed 50 days (Bishop 1941. N. Y. State Mus. Bull. 324:1-365).

SAURIA

CROTAPHYTUS COLLARIS COLLARIS (Eastern Collared Lizard). **SEASONAL ACTIVITY.** In most of the range of *Crotaphytus collaris*, emergence from winter dormancy usually occurs between late March and early April. However, *C. c. collaris* could appear sooner if favorable climatic conditions were present. To my knowledge, the following report represents the earliest activity record for *C. c. collaris*.

On 19 February 1986 in Somervell Co., Texas, 12.4 km NE Glen Rose off U.S. 67 on co. rd. 406, a young adult male *C. c. collaris* (SVL = 81 mm) was observed basking on an exposed (southwest-facing) cherty limestone outcropping at ca. 1100 h. As I approached the lizard, it took shelter under a nearby tire innertube. I removed the lizard and used a Schulteis quick-reading thermometer to obtain a cloacal temperature of 35.6° C (air temperature = 25.8° C; substrate temperature = 36.2° C). The lizard appeared to be in good condition, and as part of an ongoing investigation of saurian hematozoans, blood samples were taken from a toe-clipped digit (also used to permanently mark the specimen). I photographed and released the lizard.

Numerous investigations on the ecology of *C. c. collaris* have included information on seasonal activity of the species. Interestingly, only the related reticulate collared lizard *(C. reticulatus)* of extreme southern Texas and adjacent Mexico has been reported to emerge sooner (Feb. 8; Montanucci 1971. Herpetologica 27:183-197). This instance of early emergence by a collared lizard in northcentral Texas is nearly one month prior to previous reported dates of emergence. I have previously found hibernating *C. c. collaris* in shallow limestone hibernacula (McAllister 1983. Herp. Review 14:73-74) on 1 March at an air temperature of 29.4° C; the earliest record of activity was 10 April (air temperature = 30.6° C).

I thank Mr. Jim Riddle for access to his property and Stephen P. Tabor for assistance in collecting. I also thank Dr. Stanley E. Trauth for critically reviewing this note.

Submitted by **CHRIS T. MCALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical Center, 4500 S. Lancaster Road, Dallas, Texas 75216, USA ●

PLICA UMBRA. **NESTING.** On 17 September 1983, we found 2 egg shells and one egg of *P. umbra* in the hollow shell of the rachis of a dead palm frond which was draped over a branch 150 cm above the ground in primary rainforest 25 km E of Manaus, Amazonas, Brazil. A fourth egg was on the ground below the palm and apparently had recently fallen there. The egg shells had small slits in the ends, indicating that the eggs had hatched and were not victims of predation. The egg on the ground appeared to have been laid recently and showed no sign of development. The egg in the leaf contained a fully-formed lizard which subsequently hatched. The hatchling measured 3.8 cm SVL, 11.4 cm TL, and had a mass of 1.54 g. On 23 September 1984, A. Andrade A. Filho found two eggshells and two eggs of *P. umbra* in the leaf litter accumulated among the leaf bases of a sessile palm ca. 1 km from the first nest. One egg hatched the same day and the other hatched between one and three days afterward.

Plica umbra normally produces 2-3 eggs per clutch (Hoogmoed 1973. The Lizards and Amphisbaenians of Surinam. Dr. W. Junk, The Hague: 419 pp; Rand 1982. Clutch size in Brazilian iguanid lizards. Herpetologica 28:171-178). In each nest reported here there were eggs at different stages of development. Either the species nests communally or females reuse nest sites.

Submitted by **WILLIAM E. MAGNUSSON** and **ALBERTINA P. LIMA,** Departamento de Ecologia, Instituto Nacional de Pesquisas da Amazônia, Caixa Postal 478, 69000 Manaus, Amazonas, Brazil ●

SERPENTES

CROTALUS SCUTULATUS SALVINI (Huamantlan Rattlesnake). **BEHAVIOR.** Rattlesnake behavior is generally considered stereotypic, although behavioral variations do exist. Some of these differences in behavior (courtship, combat, etc.) might be considered slight while others are distinctive and of special interest. We have observed a unique behavior in four specimens of *C. scutulatus salvini* in which the neck region is spread laterally in a "hood-like" display without flattening the rest of the body. This behavior is quite striking and has been observed in both males and females. Only the anterior portion of the neck is flattened, exposing the lighter interspaces between the scales (Fig. 1). This neck flattening behavior is different from the body flattening known to occur in several rattlesnake species, including *C. s. scutulatus* (Mojave rattlesnake). It differs significantly from the behavior reported by Armstrong and Murphy (1979. The Natural History of Mexican Rattlesnakes, Mus. Nat. Hist. Spec. Pub. 5:1-88, Lawrence) in which an adult *C. s. scutulatus* flattened its head and trunk against the substrate and elevated its tail without rattling, a behavior we have frequently observed. It also differs from the bloating of the neck or body regions, which Carpenter and Ferguson (1977. *In:* Biology of the Reptilia, C. Gans and W. Tinkle, eds., Academic Press, NY, Vol. 7: p 506.) recognized as sterotyped behaviors in several rattlesnake forms, including *C. s. scutulatus*.

FIGURE 1. Neck-spreading behavior of *Crotalus scutulatus salvini* in threat posture.

This neck-spreading display in *C. s. salvini* appears to be a defensive or threatening posture, sporadically exhibited when the snake is provoked or threatened. The behavior occurred more frequently and was most notable in one aggressive male while standing its ground in a lateral "S" position (Fig. 1). It would maintain the neck-spread for up to three minutes. However, the display has also been observed on two occasions in an extremely docile specimen. On neither occasion did this snake rattle or pose defensively. Both incidences occurred while the snake

was being removed from its cage and lasted ca. three seconds. Another specimen in the field refused to coil, but flattened its neck while retreating backwards, with the anterior portion of its body elevated ca. 30° above the substrate. This snake remained directionally oriented to the collector and the peculiar position appeared similar to the defensive posture rattlesnakes assume against kingsnakes.

The *C. s. salvini* discussed in this report were collected in the vicinity of El Limon Totalco near the border of the states of Puebla and Veracruz, Mexico. We thank the Direccion General de Fauna Silvestre, Republica de Mexico for permits issued in 1975, which made these observations possible.

Submitted by **JAMES L. GLENN,** Venom Research Laboratory, Veterans Administration Medical Center and Hogle Zoological Gardens, Salt Lake City, Utah 84148, USA. and **HOWARD E. LAWLER,** Lower Vertebrate Department, Arizona-Sonora Desert Museum, Tucson, Arizona 85743, USA ●

ELAPHE VULPINA VULPINA (Western Fox Snake). **BEHAVIOR.** Aggregations of gravid or hibernating *Elaphe v. vulpina* have been reported by Smith (1961. Ill. Nat. Hist. Surv. Bull. 28(1):208) and Vogt (1981. Natural History of Amphibians and Reptiles in Wisconsin, Milwaukee Public Museum, Milwaukee, WI pp. 138-140.).

On 2 July 1984 an aggregation of 16 *E. v. vulpina* were found at 1800 h beneath a large (1.5 m x 2.0 m) piece of metal (portion of a silo roof) lying on the ground in an abandoned barnyard in DuPage County, IL. The surrounding habitat was disturbed prairie and reclaimed agricultural land. The temperature was 70-75° F with a heavy overcast. With the exception of one subadult female, all of the snakes were gravid and of average size (1.0 -1.3 m). Most of the snakes were coiled individually in depressions beneath the metal groundcover although several were lying in mouse runs. Upon exposure, none of the snakes made any effort to escape to the tall grass surrounding the metal, although two individuals attempted to escape down rodent burrows. The piece of groundcover described has frequently harbored fox snakes, especially on cool days or during evening hours. However, males as well as females would be found, and the number of specimens at any one time would never exceed three or four. On this and other occasions *Thamnophis radix* and *Thamnophis sirtalis semifasciatus* were found in association with the *E. v. vulpina*. The largest female *E. v. vulpina* was collected, and she deposited 24 adherent eggs on 13 July 1984, all of which hatched on 28 August 1984. The female and hatchlings were subsequently released at the above location.

Submitted by **ROBERT A. YOUNG,** University of Mississippi Medical Center, Jackson, Mississippi 39216, and **TERRY L. VANDEVENTER,** Director, Living Reptile Museum, Clinton, Mississippi 39056, USA ●

HYPSIGLENA TORQUATA JANI (Texas Night Snake). **BEHAVIOR.** Recent accounts have documented stereotypical behavioral responses of the night snake to perceived predatory threats (Mitchell 1985. Herp. Review 16:55-56; Hayes 1985. Herp. Review 16:79-81). I captured 136 *H. t. jani* in pitfall traps over a 6-year period during the course of a study on lizard ecology in southcentral New Mexico. Most snakes reacted to being removed from a trap by writhing and rapid crawling movements, but at least 11 exhibited an unusual coiling response, illustrated in Figs. 1-3. Snakes were not kept inordinately in hand, and the sequence typically began when a snake was placed on the ground. The final testing coil (Fig. 2) was achieved within 3-5 seconds and maintained (Fig. 3) despite such treatment as being turned upside down. Several snakes were observed for ca. 5 min after being placed under shrubs (usually *Larrea*); all snakes maintained the coiling posture until after I had left. The behavior was manifested by both juveniles and adults. The etiology of this behavior is of interest because of its low-frequency, long-term persistence in a natural population. The opportunity to make these observations was partially supported by grants from the O'Neil Fund, Carnegie Museum of Natural History. I thank Steve Wondzell for taking the photographs.

LEPTOPHIS AHAETULLA. **FOOD.** At 1230 h on 7 September 1986 we found a *L. ahaetulla* eating a gecko, *Thecadactylus rapicauda*, in primary rainforest at Reserva Florestal Ducke, 25 km E of Manaus, Amazonas, Brazil. The snake (SVL 73 cm, TL 125 cm, mass 43 g) had already swallowed the tail but released the gecko (SVL 10.5 cm, mass without tail 21 g) when we approached. Both animals were marked and released. Our observation confirms that *L. ahaetulla* is diurnally-active and that nocturnally-active vertebrates are common prey items (Cunha O.R. and F.P. Nascimento, 1978. Ofidios da Amazônia, VOL 10 As cobras da região leste do Pará, Publ. Avulsas Mus. Paraense Emílio Goeldi 31:102-104) suggesting that it seeks out nocturnal reptiles and amphibians in their diurnal refuges.

Submitted by **J-M HERO** and **W. MAGNUSSON,** Dept Ecologia, Instituto Nacional de Pesquisas da Amazônia, Caixa Postal 478, 69000, Manaus, Amazonas, Brasil ●

STORERIA DEKAYI DEKAYI (Northern Brown Snake). **BEHAVIOR.** Head hiding and death feigning are defensive displays exhibited by many species of snakes when confronted by a potential predator (see review by Carpenter and Ferguson 1977, *In*: Gans and Tinkle, eds. Biology of the Reptilia, Academic Press, New York Vol. 7, pp. 335-554). In this note I report both of these displays for the first time in *Storeria d. dekayi.*

On 26 April 1986, I captured a ca. 26 cm *S. d. dekayi* at Point Pelee National Park, Ontario, as it crawled across a path. After placing the snake on the ground and poking at its body with my fingers for about 90 sec, the snake responded by hiding its head under coils of the body.

I captured a second ca. 10 cm individual underneath corrugated metal at the University of Michigan Biological Station (UMBS) near Pellston, Michigan, on 7 July 1986. When I placed this individual on a dirt road and attempted to photograph it, the snake repeatedly crawled off. After several recaptures over 5 min, the snake's body ceased moving and became flaccid; the snake refused to move or turn over even when placed on its back. After the snake was returned to its cage, normal activity resumed, suggesting that it had been feigning death. When I released the snake on 11 July, I placed it on the ground and repeatedly poked at it with my fingers; after ca. 60 sec it responded by hiding its head.

On 16 August 1986, I captured a third ca. 21 cm individual at the same location where I caught the second snake. When placed on the ground and prodded with fingers, the

snake responded by hiding its head after about 120 sec.

Head hiding has not been previously reported in any snakes from the genus *Storeria*. All three of the *S. d. dekayi* individuals which I caught attempted to escape; only after a period of time when the snakes were unable to escape did they exhibit head hiding, suggesting that head hiding is a secondary escape method used only when flight is no longer possible. In contrast with *S. d. dekayi*, none of three northern redbelly snakes (*S. o. occipitomaculata*) (12-17 cm total body length) which I caught in July 1986, at UMBS and Wilderness State Park, Michigan, exhibited head hiding or death feigning when prodded with fingers for several minutes.

The scarcity of reports of death feigning in *S. dekayi* suggests that death feigning is rare in this species.

This study was suported by a grant-in-aid from the University of Michigan Biological Station.

Submitted by **FLOYD E. HAYES,** University of Michigan Biological Station, Pellston, Michigan 49769, USA. Present address: 11208 Montgomery Road, Beltsville, Maryland 20705, USA ●

TESTUDINES

GRAPTEMYS VERSA (Texas Map Turtle). **MAXIMUM SIZE.** Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin Co., Boston. 429 pp.) gave a maximum size of 127 mm CL for *Graptemys versa*.

During June and July of 1986, a mark-recapture study was begun on the turtle population of the South Llano River on the Texas Tech University Center at Junction, Kimble Co., Texas. The South Llano River of the Edwards Plateau region is a tributary of the Colorado River in which *Graptemys versa* is an indigenous species.

A total of 170 turtles was tagged and released, including a series of 42 *Graptemys versa*. Eight female *Graptemys versa* had CL measurements greater than previously reported: 134 mm, 136 mm, 137 mm, 146 mm, 151 mm, 167 mm, and two with CL of 171 mm. The mass of the largest female was 581 g. Photographs of the largest turtles were taken before release as a record of their size.

The mark-recapture project was funded by The Texas Tech University Graduate School—Texas Tech Center at Junction Summer Faculty/Student Summer Grant and by the International Center for Arid and Semi-Arid Land Studies.

Submitted by **JOEL M. MCKINNEY,** Department of Biological Sciences, Texas Tech University, Lubbock, Texas 79409, USA ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Curent Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged). Photographs may substitute for a preserved specimen only when the live specimen could not be collected, e.g. it was a protected species or it was found in a protected area. Photographs must be deposited in a university or museum collection and the catalog number(s) provided.

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

LIVE CRICKETS!

For a number of years Fluker's Cricket Farm has been a major supplier of crickets to universities and zoos throughout the United States. Crickets — scientific name *Acheta domesticus* (L.) — are a valuable nutritional supplement to the diet of many animals (crude dryweight analysis is 60% protein, 35% lipid, and 5% carbohydrate). They make an excellent food for reptiles, amphibians, frogs, small animals, fish, spiders, large insects, etc. The advantages of using Fluker's crickets are many as you can see by the following excerpts from letters we have received:

"We have had good luck in using the crickets. Many of our animals (lizards and mammals) have shown healthy improvement since the crickets have been added to their diets."

MR. ROBERT J. FRUEH
CURATOR OF THE ST. LOUIS ZOOLOGICAL PARK
ST. LOUIS, MISSOURI

"Here is an ideal feed item for many zoo animals. They are soft-bodied and thus have an advantage over meal worms whose hard outer shell is often indigestible and clogs up the intestines of animals."

MR. LAWRENCE CURTIS
FORMER DIRECTOR OF THE OKLAHOMA CITY ZOO
OKLAHOMA CITY, OKLAHOMA

"I wish to express my thanks to you for your excellent service. Your prompt deliveries have helped me very much!"

MR. J. ROTTER, BASEL, SWITZERLAND

"I consider your service a very valuable one for the scientific community, and hope it continues to grow and prosper. Its existence *(and your being able to ship year-round to Calgary)* is vital to my research program and I am sure to many others."

DR. LEON BROWDER
ASSISTANT PROFESSOR OF BIOLOGY,
THE UNIVERSITY OF CALGARY
CALGARY, ALBERTA, CANADA

We offer crickets in a variety of sizes and stages, from 1-day (1/8") to 6 weeks old (1").

Our crickets are $12.00 per thousand, or a minimum order of 500 for $9.00 plus postage. SHIPMENTS ARE MADE YEAR-ROUND WITH GUARANTEED LIVE DELIVERY. During extreme cold weather, shipments are made in a special insulated container to ensure live delivery.

Whatever your need for crickets, whether for animal feed or laboratory use, we offer fine, healthy specimens. Our company takes pride in good service, offering individual attention and efficient shipping. We would appreciate an opportunity to serve you with a standing order, or as you need them.

Fluker's Cricket Farm, Inc.

NEW DISTRIBUTIONAL RECORDS FOR REPTILES AND AMPHIBIANS IN BROWN COUNTY, WISCONSIN

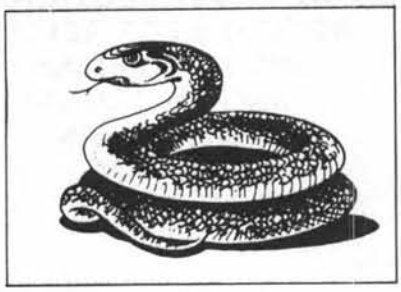
Relatively little attention has been paid to the herpetofauna of Brown County in northeastern Wisconsin, with published documented records for only *Rana pipiens, R. clamitans,* and *Thamnophis sirtalis* (Vogt 1981). In addition, eight species of anurans *(Bufo americanus, Hyla crucifer, H. versicolor, Pseudacris triseriata, Rana catesbeiana, R. clamitans, R. pipiens, and B. sylvatica)* were reported from Brown County, based on data collected by R. M. Korb, as part of a statewide acoustic survey of breeding choruses (Mossman and Hine 1984. The Wisconsin frog and toad survey: establishing a long-term monitoring program. Wisconsin Dept. of Nat. Res., Bureau of Endangered Resources. 13 pp.): these records are based on calling males and are not substantiated by preserved specimens. The purpose of this note is to present new information on the Brown County herpetofauna, based on recent collections and specimens that have accumulated at the St. Norbert College Biology Department and the Bay Beach Wildlife Sanctuary.

All preserved specimens listed below have been cataloged in the University of Wisconsin-Madison Zoological Museum (UWZM) or the Bay Beach Wildlife Sanctuary (BBWS). The former were verified by P.A. Cochran; the latter were verified by R.M. Korb.

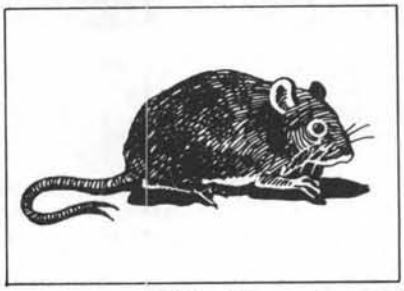
ANURA

BUFO AMERICANUS (American Toad). Wooded area immediately south and east of the exit from U.S. Highway 41 to State Highway 32 (Lombardi Avenue) (T-24N, R-20E, Sec. 33). 16 August 1984. P.A. Cochran, J.A. Cochran and A.G. Cochran. (UWZM-H 22611).

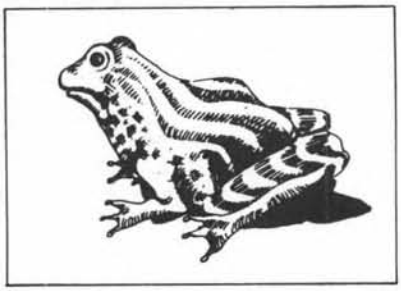
HYLA VERSICOLOR (Gray Treefrog). Baeten's woods (T-23N, R-20E, Sec. 7). April or May 1978. J.R. Hodgson. (UWZM-H 22612).



PSEUDACRIS TRISERIATA (Striped Chorus Frog). Temporary pond between St. Norbert College baseball field and C. and N.W. railroad tracks, De Pere (T-23N, R-20E, Sec. 28). April 1976 or 1977. J.R. Hodgson. (UWZM-H 22613).

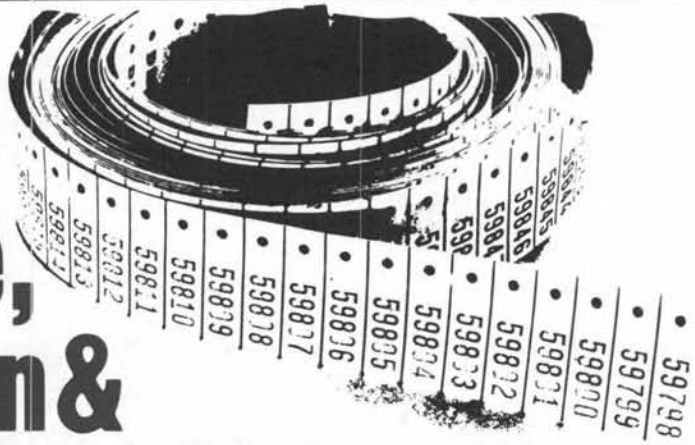


RANA SYLVATICA (Wood Frog). Wooded area immediately south and east of the exit from U.S. Highway 41 to State Highway 32 (Lombardi Avenue) (T-24N, R-20E, Sec. 33). 16 August 1984. P.A. Cochran, J.A. Cochran and A.G. Cochran. (UWZM-H 22614).



CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander). Wooded area immediately south and east of the exit from U.S. Highway 41 to State Highway 32 (Lombardi Avenue) (T-24N, R-20E, Sec. 33). 26 August 1984. P.A. Cochran and J.A. Cochran. (UWZM-H 22615).



PLETHODON CINEREUS (Redback Salamander). Ravine downstream from Kittel's Falls (T-23N, R-21E, Sec. 32). 8 September

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Stop your searching. Here are those identification tags you've been looking for. Save time, money and patience simply by ordering them right now from the NATIONAL TAG COMPANY. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on both sides.

*Note: Stock tags are consecutively numbered, but the starting number will vary for each shipment. There's no printing on back side. Custom tags can get any numbering sequence desired, with or without prefix letters, plus printing on the back side (illustration above).

NATIONAL TAG COMPANY, 815 S. Brown School Rd., Vandalia, OH 45377

REPTILE & SPECIMEN IDENTIFICATION TAGS

Size: 1"x¼"

1984. J.A. Cochran, P.A. Cochran, J.R. Hodgson, A.G. Cochran and J.Y.S. Hodgson. (UWZM-H 22616).

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). Duck Creek, Brown County Park (T-24N, R-19E, Sec. 25). 8 May 1985. J.R. Hodgson and J.A. Cochran. (UMZM-H 22627).

CHRYSEMYS PICTA MARGINATA (Midland Painted Turtle). Duck Creek, Brown County Park (T-24N, R-19E, Sec. 25). Late spring, 1983. W. Baeten. (UWZM-H 22617).

CLEMMYS INSCULPTA (Wood Turtle). Trout Creek (T-24N, R-19E, Sec. 15, NE 1/4). 30 April 1982. R.M. Korb. Shell preserved in BBWS collection (RE 016). State Highway 29 just west of County Road FF (T-24N, R-20E, Sec. 12). 19 May 1985. P.A. Cochran and J.R. Hodgson (UWZM-H 22628).

EMYDOIDEA BLANDINGI (Blanding's Turtle). Bay Beach Wildlife Sanctuary, Green Bay (T-24N, R-21E, Sec. 29). April 1982-March 1985. R.M. Korb. Several photographs in BBWS collection (J 1108-J 1120, J 1201-J 1204).

PSEUDEMYS SCRIPTA (Slider). East River at Mason Street Bridge in Green Bay, 28 March 1981. R.M. Korb. Shell preserved in BBWS collection (RE 01). Undoubtedly an escaped or released pet.

SERPENTES

DIADOPHIS PUNCTATUS (Ringneck Snake). Baeten's woods (T-23N, R-20E, Sec. 7). 22 May 1971. M. Baeten, (UWZM-H 22618).

ELAPHE VULPINA (Fox Snake). State Highway 57 and County Road A (T-25N, R-22E, Sec. 29). R. Zimmerman. Adult held alive in BBWS display (RE 233) and photograph on file (J 1219).

LAMPROPELTIS TRIANGULUM (Milk Snake). Brosig Street, Green Bay (T-23N, R-21E, Sec. 9). 25 September 1983. L. Russell. Preserved in BBWS collection (RE 09).

OPHEODRYS VERNALIS (Smooth Green Snake). Bay Beach Wildlife Sanctuary, Green Bay (T-24N, R-21E, Sec. 29). 14 September 1972. G. Bunker. (UWZM-H 22619).

STORERIA DEKAYI (Brown Snake). Green Bay. 13 October 1981. Preserved in BBWS collection (RE 08).

STORERIA OCCIPITOMACULATA (Redbelly Snake). Abandoned mink ranch south of County Road G (T-23N, R-21E, Sec. 32). 28 April 1971. G. Bunker. (UWZM-H 22620). 6 May 1974. J.R. Hodgson. (UWZM-H 22621).

THAMNOPHIS SIRTALIS (Common Garter Snake). Abandoned mink ranch south of County Road G (T-23N, R-21E, Sec. 32). 25 June 1971. G. Bunker and J.R. Hodgson. (UWZM-H 22622). 29 September 1971. J. Hinkley. (UWZM-H 22623).

We thank all individuals who contributed specimens and Andrew Cochran, Joseph Cochran, and Jay Hodgson for assistance in the field.

BOOK REVIEWS

Species of Special Concern in Pennsylvania, edited by Hugh H. Genoways and Fred J. Brenner. 1985. Special Publication No. 11 of the Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. vi + 430 pp., illus. + maps. $30.00.

State-based biological surveys are a nationwide trend, founded on the rationale that efforts to protect native species are often initially most effective when carried out at the state level. This publication presents the results of an assessment of Pennsylvania's flora and fauna by the recently formed (1979) Pennsylvania Biological Survey, an organization created by the National Audubon Society in collaboration with Pennsylvania's Game Commission, Fish Commission, and Department of Environmental Resources. More than fifty biologists, both amateur and professional, affiliated with almost thirty different academic institutions, volunteered their time and expertise to contribute to this large (21 x 28 cm), clearly organized and well-illustrated reference.

The book begins with three excellent, although technically challenging, introductory sections that describe Pennsylvania's aquatic and terrestrial habitats, physiographic provinces, and drainage patterns. Because so much of the problem of species protection is based on habitat preservation, these sections provide the habitat descriptions and the specific example localities that in turn give perspective and focus to attempts to preserve especially unusual areas within the boundaries of the Commonwealth.

The book presents the results of the survey and follows the overall organization of a successful survey published several years ago by the state of Florida. The Pennsylvania survey uses the same large taxonomic divisions (plants, invertebrates, fish, amphibians and reptiles, birds, mammals); the same status categories (endangered, threatened, vulnerable, undetermined, extirpated, recently extinct) and the same format for individual species (description, range, habitat, basis of status classification, recommendations).

Each large taxonomic division is given a separate chapter, and each of these chapters represents the efforts of a different subcommittee. The choice of these taxonomic divisions reflects the public interest in the orga-

nisms within each division, and the information available on those organisms, rather than the actual endangered species in each division. Consequently, the survey has one chapter on plants, one chapter on invertebrates, and four chapters on vertebrates. Because the total number of Pennsylvania vertebrates is reasonable, the subcommittees that compiled the four vertebrate chapters can be confident that most species deserving of special concern have been identified, categorized, and described. The sheer number of Pennsylvania plant species presented problems to the subcommittee attempting to survey for plants at risk, and in the case of the invertebrate subcommittee, the vast numbers of invertebrate species, coupled with the limited information available on invertebrate distribution and abundance in Pennsylvania, proved to be overwhelming. The plant subcommittee dealt successfully with their dilemma by limiting their survey to vascular plants, but the invertebrate subcommittee carried the concept of limited coverage too far and opted to designate only species in those taxonomic categories that represented areas of expertise for individual committee members. Despite the committee's explanation of this decision in the introduction to the invertebrate chapter, a list of invertebrates at risk that has one flatworm species (Refton cave planarian) and 61 insect species, including 34 from the Order Odonata (dragonflies), 25 from the Order Lepidoptera (butterflies and moths) and 2 from the Order Coleoptera (beetles) is so skewed as to lose credibility.

Except for this difficulty with the selection of invertebrate species, the subcommittees have done an excellent job of reviewing appropriate literature and recruiting expert individuals to participate in the Pennsylvania Biological Survey. Each species account is written by a single expert, and the academic and field credentials of these experts are impressive. The book does a truly admirable job of summarizing the current state of knowledge for each of the species covered. The one-species, one-author format provides the reader with an easily identified source of additional information on any of the species of special concern.

The problems that exist in this book are not due to the content, which is of uniform high quality, but rather with matters of style and graphic presentation. These problems arise because the book is obviously intended for multiple audiences, ranging from professional botanists, zoologists, and ecologists, to untrained citizens of the state of Pennsylvania who are seeking information on endangered species or habitats. Because the book is the work of committees, there are stylistic inconsistencies from chapter to chapter. For example, common names are capitalized in the chapter on birds, but not in any of the other chapters. Are birds more "proper" than other organisms? More distracting are the rather subtle changes in writing style, both from chapter-to-chapter, and sometimes from species-to-species. In general, the entries in the chapters on plants, amphibians and reptiles, and birds are especially readable, perhaps because amateurs have often been involved in the study of these organisms and so communication with interested laypersons is a more frequent experience. Some contributors have difficulty giving up a formal scientific writing style that isn't appropriate in this book. For example, John S. Hall writes, in his entry on the Allegheny woodrat (p. 364): "During 1978 and 1979, John S. Hall, Albright College, conducted a survey of bat populations in caves. . . During that survey Hall (personal communication) noted a general absence of woodrat signs. . ." Laypersons not familiar with the traditions of scientific writing may wonder if there are two John S. Halls, both teaching at Albright College, or if there might be a single Professor Hall who makes appointments to communicate with himself. A minor complaint, but one that is easily clarified within the traditions of formal scientific writing, as John D. Groves did in his clearly-written description of the coastal plain leopard frog as he explained his sources of information in a much more direct fashion (p. 264): "The following information is derived from published statements. . .and from personal observations of this species in Maryland."

The layout of the book is unnecessarily awkward. Like other recent volumes in the Carnegie Museum Special Publication series, it is based on a two-column per page format. In this case, however, the two columns are frequently interrupted by page-wide, or at least more than one-column-wide, photographs and state maps. These illustrations create disruptive blank spaces along the sides of the pages, which, when coupled with visually indistinct headings for individual species, make locating species and reading the entries unusually difficult. In almost all of these situations, the problem could have been easily avoided by reducing the state maps and the photographs to one-column width (as has already been done very effectively with the North American distribution maps that accompany each entry), and placing them consistently within the text on each species.

The illustrations are sometimes poorly designed or conceptually misleading. The "Map of Pennsylvania streams" (p. 32) is actually a diagram of watershed boundaries, and the state maps that accompany each species lack county names, so it is difficult to relate the county-based text account of locations to the state map. Some of the illustrations would have benefited from the aids to graphic design and lettering that have recently become widely available.

These lapses in presentation do not detract from the scholarship or the effectiveness of the book as a scientific reference, but they are aspects that may disappoint laypersons who have become used to higher standards in their sourcebooks. Popular writing in natural history is now frequently quite eloquent, as demonstrated by authors as diverse as David Attenborough, Lewis Thomas, John McPhee, and Stephen Jay Gould, and graphic presentation has become quite sophisticated, as exemplified by the books produced by The National Geographic Society and also by most of the popular field guides, especially those edited by Roger Tory Peterson. Consequently, the stylistic shortcomings of "Species of Special Concern in Pennsylvania" may limit its appeal to one of its major intended audiences.

For scientists, however, the volume is of unquestionable value. Not only does it provide a wealth of information about Pennsylvania species and the persons who study them, but it also represents, as the published version of the Pennsylvania Biological Survey results, a major step in the protection and preservation of endangered species within the Commonwealth. The persons drawn together by the Survey form a core group to monitor the progress of conservation within the state. Taken together with biological surveys in neighboring states, and growing pressure for a national biological survey, the project is a hopeful sign for the preservation of habitats and species in the heavily industrialized northeastern United States.

The Tungara Frog: A Study in Sexual Selection and Communication, by Michael J. Ryan. The University of Chicago Press. 1985. $14.95 paper, $33.00 cloth.

This study on the reproductive behavior of the tungara frog demonstrates that females preferentially choose larger males because the 'chuck' portion of their mating call has a lower frequency. On the other hand, the 'whine' portion of the call is sufficient for species recognition. Increasing the number of 'chucks' makes for an increasingly attractive mating call to the female; competition from neighboring males will stimulate complexity of the call. However, the fringe-lipped frog-eating bat selects complex-calling frogs and so a compromise between maximizing mate attraction and minimizing predation has evolved.

These are but some of the interesting results of this well-documented study made in both field and laboratory. It definitely establishes the intricacies of anuran mating systems and should reactivate studies on the details of mating in our "better known" frogs—the formerly accepted view of the passive role of the female is now obsolete. This is an exciting book that exemplifies the better aspects of field observation, that introduces new dimensions to the comprehension of anuran communication, the role of female choice, the effects that calling has on predation and energetics and the benefits of forming aggregations, and that discusses the role selection has had in molding these activities. It is must reading for herpetologists, especially those not up on mating strategies in frogs.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1986

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Herpetological Review

Volume 17 December 1986 Number 4

29TH ANNUAL MEETING HELD AT SOUTHWEST MISSOURI STATE UNIVERSITY

The 1986 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League in Springfield, Missouri, USA, during 10-15 August. Local Committee Co-Chairmen Robert Wilkinson and Don Moll hosted a relaxed, but informative, gathering of herpetologists from around the world on the campus of Southwest Missouri State University.

SSAR BOARD OF DIRECTORS MEETING

The annual meeting of the Board was held on Sunday, 10 August, under the chairmanship of SSAR President Sherman Minton. All Board members were present plus other officers, editors, committee chairs, and guests. The Board met for 7 hours and discussed annual reports submitted by each Society officer, editor, committee, and coordinator. The financial status of the Society was the primary topic of discussion throughout the meeting. Decisions of the Board were announced at the annual business meeting of the Society and are described in the following information.

BUSINESS MEETING

A. Call to Order

President Sherman Minton called the 1986 business meeting of the Society for the Study of Amphibians and Reptiles to order at 16:44 h on 12 August in room 2 of Temple Hall on the campus of Southwest Missouri State University in Springfield.

B. President's Report:

President Minton made the following statement regarding the financial state of the Society. During the past several years, the Society has financially emulated the Federal government. The Society was operating approximately one-half a fiscal year ahead relying on increases in membership to maintain adequate cash flow. Since membership has plateaued, such a management technique is too risky to continue. Some Society budgets have also been overexpended. A long-standing investment of $15,000, which had been yielding a high rate of return, unexpectedly collapsed. The value of the bonds remains in question since both companies are involved in bankruptcy proceedings. In view of this series of events, it has been necessary to take certain remedial steps. The 1986 budget has been reduced by approximately 15%, with finances to be reviewed in March and budgetary cuts restored as much as possible. There has been a modest increase in dues; this change was approved by the Board prior to the change in our investment portfolio. There will be a decrease in the number of pages in the *Journal of Herpetology*. This reduction will be offset partially by using different techniques in layout and printing of the *Journal* which results in an increase of approximately 4% more words per page. Grants-in-Herpetology awards have been curtailed for 1987. Donations and proceeds from the 1986 Herpetology Exam held during the Springfield meeting will be used to fund at least one graduate student category grant. SSAR hopes to restore the grants program as originally conceived in all or most categories during 1988.

C. Secretary's Report

Secretary James Jacob stated that he would not review actions taken at the annual meeting of the Board of Directors since all major decisions are being announced during the Business Meeting. He did, however, announce that a membership campaign aimed at members of regional herpetological societies would be undertaken. The campaign will enlist the aid of regional societies by permitting them to retain $2 from the dues of each of their members who becomes a member of SSAR through the regional society. He encouraged SSAR members with contacts among regional herpetological societies to promote this program, pointing out that it is beneficial to both SSAR and the regional organizations.

D. Treasurer's Report

Treasurer Henri Seibert pointed out that most of the items pertaining to the fiscal status of the Society had been announced by the President. He did, however, make the following announcement: (1) Because of increased production costs, the Board found it necessary to increase dues by $5 for regular members, $3 for student members, and $10 for institutions. Sustaining membership will be $50; contributing will be $75. (2) Fiscal management of the Society is being changed so that only receipts from one fiscal year can be used for expenses incurred during that same fiscal year. In the past, money from one fiscal year has been used to pay bills from another fiscal year. The 1986 budget has been reduced to approximately $78,100 in order to meet the new fiscal management format. As a result, we will have to pare expenditures to a bare minimum; and there will be a temporary decrease in some ancillary services normally provided by the Society. (3) The SSAR membership list is now being maintained on a Society microcomputer at the office of the Treasurer. We can now produce our own mailing labels. This capability should help eliminate recent problems with the mailing list which occurred while the list was being maintained by Allen Press. We will save $2,000 per year by maintaining our own membership list. (4) The Treasurer announced that the Board approved offering life memberships again. Seibert asked James Christiansen, Chair of the SSAR Long-range Planning Committee, to explain the offer. Christiansen stated that the Society will make life memberships available for a cost of $550 until 31 December 1986. He pointed out that members can protect themselves from future dues increases by taking advantage of this offer. Individuals in the 27% tax bracket will receive a tax break of $150, thereby reducing the real cost to $400. Life membership funds will not be used to finance current operations; rather, they will be placed in a separate fund with members' annual dues being paid from interest earned by the money. Christiansen pointed out that the life membership fund will be intensively managed in order to earn the highest possible rate of return in conservative investments. He encouraged members to take out life memberships, pointing out that now is time to take advantage of the tax break. (5) Seibert announced that members may pre-pay dues, at the current rate, for a period of up to three years. In view of the possible changes in the tax laws, pre-payment will insure a full deduction under the current statutes on the 1986 tax return. The Treasurer encouraged members to take advantage of either the pre-payment or life membership offer.

E. Publications Secretary's Report:

Publications Secretary Douglas Taylor reported that sales from his office were average. He announced that he is not selling as many copies of *Turtles of Venezuela* as he would like, but this is probably due to the fact that advertisements did not get out as quickly as we had hoped. Taylor announced that *Herpetology of Costa Rica* will be available soon. Pre-publication cost will be $25, with a regular price of $30. Herpetological Circular No. 15, *Cannibalism in Reptiles: A Worldwide Review* by Joseph C. Mitchell will be out shortly. The pre-publication price is $3; the regular price will be $4.

F. Editors' Reports

1. *Contributions to Herpetology*

Editor Kraig Adler announced that Number 3 in the Contributions to Herpetology series, Jay Savage and Jaime Villa's *Introduction to the Herpetofauna of Costa Rica* will be delayed because publication announcement did not appear in the September 1986 issue of *Herpetological Review*. Society members will be able to take advantage of the pre-publication price until 31 December 1986. Number 4 in the Contributions to Herpetology series, *Salamanders of China* by Zhao Ermi and Hu Qxiong, will be published in 1987.

2. *Facsimile Reprints in Herpetology*

Editor Kraig Adler announced that plans are underway to issue reprints of Daudin's *Histoire Naturelle des Rainettes* and Gunther's volume on reptiles and amphibians in the *Biologia Centrali-Americana* series in late 1987.

3. *Catalogue of American Amphibians and Reptiles*

Recently appointed Editor Jaime Villa announced that the *Catalogue* is on schedule for 1986. A comprehensive index will be produced soon. Villa stated that there is a need for authors for *Catalogue* accounts. He pointed out that the Society would like to complete the North American accounts as soon as possible. The Editor announced that he is undertaking an aggressive posture in order to speed the publication of accounts; and that a one-year limit has now been imposed for the production of an account. Villa stressed the usefulness of the *Catalogue* to the herpetological community, pointing out that it provides the most comprehensive summary available of a taxon. He noted that it has been necessary to publish a number of non-North American accounts because of delays in completion of North American accounts. Villa reiterated the need for volunteers to prepare accounts, stressing the need for accounts to be completed in one year. Villa encouraged potential authors to contact him.

G. Committee Reports

1. Conservation Committee

President Minton announced that the Conservation Committee is working on a system for assigning monetary value to amphibians killed in environmental accidents. The document will be comparable to one which has already been prepared for fishes. Minton commented that the Committee may expand the system in the future to include reptiles.

2. Meeting Sites Committee

President Minton announced that SSAR has accepted an invitation from Richard Vogt to host the 1987 annual meeting in Veracruz. The Society also accepted an invitation from the University of Michigan to participate in a three-way meeting of SSAR, the Herpetologists' League, and the American Society of Ichthyologists and Herpetologists in Ann Arbor in 1988. Dates for the meeting are still under discussion.

At the request of President Minton, Vogt discussed plans for the Veracruz meeting. He pointed out that a meeting in Mexico will be at a slower pace than many of our previous gatherings. Meeting announcements will be mailed out in January. Deadlines for pre-registration and submission of contributed papers will be in May. The meeting site will be the Hotel Mocambo, which is located in the southern part of Veracruz. The hotel has 110 rooms, beach access, tennis courts, and is located approximately 400 meters away from another hotel which has 400 rooms. A trailer park is located within 2 km of the hotel. Food at the hotel will be under the control of the Local Committee, but there are a number of restaurants nearby. A number of historical sites are close to the city. Field trips to these areas, as well as to the biological station at "La Tuxtlas," Mount Orizaba, and other sites will be available. Collecting for non-scientific reasons will not be permitted, but information will be sent to pre-registrants regarding application for permits. Information on travel arrangements to Veracruz will be forthcoming.

3. Grants-in-Herpetology

Sandy Echternacht announced the Grants-in-Herpetology awards for 1986. **Graduate Student Herpetological Research:** Barry Sinervo (University of Washington) "Thermal physiology of growth in field populations of *Sceloporus* lizards: Genetic and environmental aspects"; John L. Carr (Southern Illinois University) "Phylogenetic analysis of the Neotropical emydid genus *Rhinoclemmys*." **Herpetology-oriented Conservation:** Franz J. Kutka (Iowa State University) "The threat of habitat acidification to the Ambystomatid salamanders of Michigan." **Field Work:** Byron Wilson (University of Washington) "A study of latitudinal patterns of mortality in *Uta stansburiana*."

4. Kennedy Award

President-elect Norman J. Scott announced that Shawn R. Crowley of the University of New Mexico was the winner of the 1986 Kennedy Award. His article on "Insensitivity to desiccation of sprint running performance in the lizard, *Sceloporus undulatus*" was chosen as the best student authored paper or note published in the *Journal of Herpetology*.

5. Nominating Committee

President Minton presented the following slate of candidates for office in 1987 as recommended by the Nominating Committee and approved by the Board of Directors. **President-Elect:** Hugh Quinn (Houston Zoological Gardens, Houston, Texas, USA) and Edward

A Checklist with Distribution Maps of the Turtles of the World

by John B. Iverson Available October 1986

A comprehensive guide to the scientific nomenclature of the turtles of the world, including information on original citations, type specimens, type localities, distribution, and pertinent literature for all recognized species. Distribution dot maps are provided for each species. Includes about 300 pages and over 260 maps. Available only in soft cover editions. Price including surface shipping: $20.00 US. Please add $10.00 US for foreign airmail.

Address order to:

John B. Iverson
Dept. of Biology
Earlham College
Richmond, IN 47374 USA

Moll (Eastern Illinois University, Charleston, Illinois, USA). **Secretary:** James S. Jacob (Glendale College, Glendale, Arizona, USA). **Treasurer:** Henri C. Seibert (Ohio University, Athens, Ohio, USA). **Director (USA):** Lynne Houck (University of Chicago, Chicago, Illinois, USA) and Robert Aldridge (Saint Louis University, St. Louis, Missouri, USA). **Director (Non-USA):** James Bogart (University of Guelph, Ontario, Canada) and Michael R. K. Lambert (Tropical Development and Research Institute, London, UK).

President Minton called for nominations from the floor. No further nominations were made and James Christiansen moved that nominations cease. The motion was seconded by George Pisani and approved by a voice vote. A ballot will be sent to all active members by first-class mail.

6. Resolutions

On behalf of SSAR, George Pisani offered the following resolutions:

1. **Whereas** Bob Wilkinson and Don Moll most generously volunteered on reasonably short notice to host the 1986 annual meeting; and,
   Whereas they have most capably orchestrated what has been a fine, well organized and interesting meeting; and, **Whereas** various trunk airlines into Springfield have done much good for the field of herpetology by boosting the cardiovascular rate and fitness of certain of the field's most distinguished persons; therefore,
   Be it resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League offer their most sincere thanks to Bob, Don and their unnamed cadre of hardworking students who have made it possible for us to meet in Springfield.
2. **Whereas** the following persons have given generously of their time and stolen freely from departmental and personal budgets to serve SSAR in a variety of vital roles in late 1984 through 1985; and,
   Whereas they have served the Society capably; and,
   Whereas the Society hopes that by shamelessly lauding them here it can again recruit them to other tasks, therefore,
   Be it resolved that SSAR expresses its appreciation to the following individuals: George Pisani, President; Carl Gans, Immediate Past-president; Linda R. Maxson and Hugh R. Quinn, Directors; the late James P. Bacon, Chair of the Grants-in-Herpetology Committee.
3. **Whereas** the Herpetologists' League this year celebrates the 50th anniversary of their journal, *Herpetologica;* and,
   Whereas this is an outstanding milestone for any society; therefore,
   Be it resolved that the Society for the Study of Amphibians and Reptiles extends its congratulations to the Herpetologists' League on this occasion.
4. **Whereas** Stephen G. Tilley has served the Society with distinction in many essential ways over the years; and,
   Whereas his most recent contribution as Editor-in-Chief of the *Catalogue of American Amphibians and Reptiles* has maintained the high quality of that publication; and,
   Whereas Steve has momentarily escaped from Society work to pursue the vagaries of research; therefore,
   Be it resolved that SSAR expresses its deep appreciation to Stephen Tilley and presents him a plaque in acknowledgement thereof.
5. **Whereas** Marty Crump has again spent considerable time and effort organizing, promoting and conducting the Herpetology Exam; and,
   Whereas her determination to encourage people to forsake their egos and take the exam has resulted in the accumulation of several hundred dollars to seed the 1987 Grants-in-Herpetology Fund for SSAR; therefore,
   Be it resolved that SSAR offers its most sincere gratitude to Marty Crump for the fine work she has done.
6. **Whereas** Ben Greishaw is a most talented artist and long-time exhibitor at these joint meetings; and,
   Whereas he most generously donated his time and talents to design the logo for the Springfield meeting; therefore,
   Be it resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League extend their most sincere thanks to Ben Greishaw for his work.
7. **Whereas** the ecosystems of the Cuatro Ciénegas basin, Coahuila, Mexico, are unique and have extremely high biological value; and,
   Whereas people of the city of Cuatro Ciénegas are expressing their concern over recent construction activities currently threatening the aquatic resource values of great natural diversity in an area of the basin; therefore,
   Be it resolved that two scientific societies, the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, consisting of over 330 scientists from several coun-

tries in the international scientific community, including México, meeting jointly at Southwest Missouri State University, Springfield, Missouri, USA, on 10-15 August 1986, support any efforts of the citizens of Cuatro Ciénegas to protect and preserve the unique natural environments of the Cuatro Ciénegas basin and their rich fauna and flora.

H. Transfer of Gavel and Adjournment

President Minton asked President-elect Scott to come forward and accept the SSAR gavel as a symbol of the transfer of the Presidency which will officially take place on 1 January 1987. Scott asked if there was any further business. There being none, George Pisani moved, and Jim Jacob seconded, that the meeting being adjourned. The motion passed by voice vote and President-elect Scott declared the meeting closed at 17:26 h.

Respectfully submitted,
James S. Jacob
Secretary ●

SSAR COMMITTEES FOR 1986-1987

Following the Springfield meeting, President Minton appointed the following committees and coordinators for the current year to report to the Board at the Veracruz meeting in 1987. Individuals with important matters pertaining to the activities of Society committees should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of *Herpetological Review*.

Conservation: William S. Brown (Ch.), John L. Behler, William E. Cooper, Nat B. Frazer, M.R.K. Lambert, Paul E. Moler, Patricia Riexinger, and Peter J. Tolson.

Grants-in-Herpetology: Thomas H. Fritts (Ch.), Steven D. Aird, Robert N. Bader, Dale Belcher, Arthur C. Echternacht, Darrel Frost, and Michael V. Plummer.

Kennedy Student Award: J. Eric Juterbock (Ch.), Robert E. Gatten, Ken R. Marion, John S. Mecham, Andrew H. Price, and Laurie J. Vitt.

Long-range Planning: James L. Christiansen (Ch.), Ralph Axtell, Carl Gans, James S. Jacob, Sherman A. Minton, George R. Pisani, Henri C. Seibert, and Douglas H. Taylor.

Meetings: Henry R. Mushinsky (Ch.), James R. Dixon, and James S. Jacob.

Nominating: Kraig Adler (Ch.), Martha L. Crump, Harold A. Dundee, Max Hensley, James S. Jacob, and Martin J. Rosenberg.

Regional Society Liaison: Steven H. Hammack (Ch.), Fred Antonio, Mike Bumgardner, Brint Spencer.

Zoo Liaison: Donal Boyer (Ch.), Dennis W. Herman, James A. Hitchiner, Brint Spencer, and Ruth Zantzinger.

Association for Systematics Collections Coordinator: Max Nickerson.

Common and Scientific Names Coordinator: Joseph T. Collins.

Translations Coordinator: Robert D. Aldridge. ●

EXHIBITORS WANTED FOR 1987 JOINT SSAR-HL MEETING

The local committee for the 1987 SSAR-HL meeting in Veracruz, Mexico is in the process of contacting possible exhibitors for the meeting. Any individual or organization is welcome to display herpetologically-oriented material (except live animals). The following information may be useful to potential exhibitors.

Registrants: Biologists, college professors, zoo and museum personnel, state and federal wildlife officials, graduate students in biology and serious lay persons with interests in amphibians and reptiles.

Previous exhibitors: Publishers, used-book companies, biological supply companies, manufacturers of animal collecting and housing equipment, artists (with animal themes), tee-shirt sellers, and travel services.

Cost: $125 for each table (approx. 4x6 feet). Artists who sell materials created by themselves will be charged $125 or the equivalent in donated arts or crafts; such persons are expected to be actively engaged in their work at the exhibit area.

Colleagues in Mexico, Central and South America are urged to recruit exhibitors from their areas. Displays of native arts and crafts with herpetological themes would be particularly welcomed.

Exhibitors (or commercial organizations which will not have exhibits at the meeting) are also invited to place advertisements in the meeting program booklet. Full page, copy ready ads will cost $125; smaller ads will cost proportionately less.

For exhibit applications or further information, contact:

Ruth Zantzinger

HELP *HR* GO HT*!

As printing costs escalate, publications like *HR* face an uphill struggle to maintain content and stay within budget. The most cost-effective way to do this is to produce *HR* through the page-proof stage ourselves and thus devote 40% more of our budget to actual printing costs — the concept of "desk top" publishing. The primary benefit of this is the ability to print many more pages of *HR* per issue. The SSAR has an opportunity to split start-up cost of such a project with a University of Kansas department, and is seeking a donor of $2,000 to underwrite the *HR* share.

Interested parties are encouraged to contact the Managing Editor. Donations to the society are tax deductible.

*High Tech ●

SSAR GRANTS-IN-HERPETOLOGY — 1987

The Society for the Study of Amphibians and Reptiles announces that proposals are now being accepted for the 1987 Grants-in-Herpetology Program. This program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. In contrast to previous years in which awards were offered in several categories, awards in 1987 will be made only for graduate research projects. This restriction is due to lack of funds for this program. Other categories of awards will be re-instituted in future years if sufficient funds are available. All applicants must be members of the SSAR and are limited to the submission of one proposal per year. Two awards will be made in the Graduate Student Research in Herpetology category in 1987.

GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

Each proposal must include the following elements: A) ABSTRACT; B) BACKGROUND AND OBJECTIVES of the proposed project, in terms of its relevance to herpetology; C) METHODS of carrying out the research or conducting the project; D) ITEMIZED BUDGET for the project which should not exceed $430; E) CURRICULUM VITAE for the applicant; and F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding cover page, abstract, bibliography, budget, and curriculum vitae.

All proposals must be submitted in duplicate and postmarked no later than 1 MARCH 1987. Failure to meet the deadline or to follow the guidelines may result in elimination of the proposal from consideration. The awards will be announced by 15 April 1987. Submit proposals to:

Thomas H. Fritts, Chair
SSAR Grants-in-Herpetology Committee
U.S. Fish and Wildlife Service
Department of Biology
University of New Mexico
Albuquerque, New Mexico 87131, USA

Successful applicants will be expected to submit to the SSAR a written report of their research or project results within a reasonable time after the project year is completed. They are also encouraged to submit the results of their work for publication in the *Journal of Herpetology* or *Herpetological Review*.

Financial contributions by SSAR members, institutions, and other interested benefactors can increase the number of awards in this program. Your tax-deductible contribution to this program will be appreciated by the Society and will directly benefit meritorious research. Contact the President of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization which will match donations made to nonprofit educational organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program. ●

HR DEADLINES

Contributors of Newsnotes, Regional Society activities, Meeting notices and other dated material to ***HR*** please note: Deadlines for receipt of such material for the March, June, September and December issues are 1 January, 1 April, 1 July and 1 October, for the respective issues. ●

NEWSNOTES

SMITHSONIAN RESEARCH FELLOWSHIPS

The Smithsonian Institution announces its research fellowships for 1987-1988 in the fields of Social and Cultural History, History of Art, History of Science and Technology, Earth Sciences, Anthropology and Biological Sciences. In the biological sciences, fellowships will be awarded for studies in tropical biology, ecology, systematics, natural history, evolutionary biology, animal behavior and pathology, paleobiology, marine biology and environmental studies.

Fellowships are awarded to support independent research in residence at the Smithsonian in association with the research staff and using the Institution's resources. Stipend and tenure period vary for senior postdoctoral fellows, postdoctoral fellows, predoctoral fellows and graduate students and range up to $25,000 per year. Awards are based on merit. Applications are due 15 January 1987.

For further information, write to:
Smithsonian Institution
Office of Fellowships and Grants
Desk F
7300 L'Enfant Plaza
Washington, D.C. 20560, USA ●

GREEN TURTLE RESEARCH STATION

The Caribbean Conservation Corporation announces the availability of the Green Turtle Research Station to scientists and students desiring accommodations and support for field research on the northern Caribbean coast of Costa Rica. During July, August and September the Station serves as the field quarters for Dr. Archie Carr's research on the Atlantic green sea turtle *(Chelonia mydas mydas)*. With the employment of a full-time bilingual manager the CCC is able to keep the Station open the year round for research and field classes. The Station can accommodate up to 16 people in private dormitory rooms. Food is provided by a full-time cook in a communal dining room. Boats are available for groups and individuals.

For further information contact:
David Carr, Executive Director, CCC
P.O. Box 3942
Tallahassee, Florida 32315, USA ●

ECOLOGY/CONSERVATION FELLOWSHIPS

The MORTON B. RYERSON FELLOWSHIP is established through funds contributed by the Chicago Community Trust. Applications are being solicited for fellowships-in-residence to begin anytime in 1987.

Open to any student, with preference to graduate students, the fellowship awards a monthly stipend of $800, plus room, for any period from two to nine months. Fellows are granted full and private use of a comfortable four-room log cabin with kitchen, spectacularly situated amidst floodplain, hardwood forest on the banks of the DesPlaines River in the Edward L. Ryerson Conservation Area, managed by the Lake County Illinois Forest Preserve District.

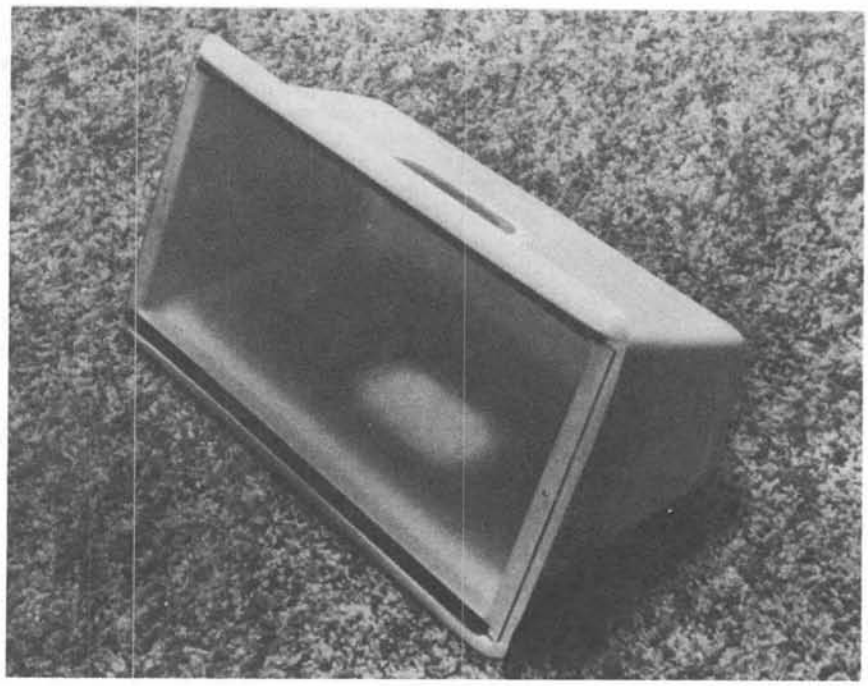
Fellows will be expected to conduct independent field research on any topic relating to ecology and/or conservation in northern Illinois forests. Cooperation with a local interpretive nature center is encouraged, but the research project is paramount.

Applicants should send a two to three page proposal, a resume or CV, two letters of recommendation, and a proposed schedule of residency at the Ryerson Conservation Area.

Address application or requests for complete fellowship description to:
Dr. John W. Fitzpatrick
Chairman
Morton B. Ryerson Fellowship
Committee
Department of Zoology
Field Museum of Natural History
Roosevelt Road at Lake Shore Drive
Chicago, Illinois 60605, USA

Deadline for receipt of 1987 application is 1 February 1987. ●

LEGISLATIVE ALERT



Proposed reclassification of ranched Nile crocodile populations in Zimbabwe from endangered to threatened by similarity of appearance. The U.S. Fish & Wildlife Service proposed (7 March 1986, FEDERAL REGISTER; comment period closed 10 July 1986) to reclassify ranched populations of *Crocodylus niloticus* under section 4 of the Endangered Species Act. At present, there are five crocodile ranches in Zimbabwe. Ranched specimens, after reclassification under CITES from Appendix I to Appendix II in 1983, may be traded commercially under export permit from the country of origin and the permit requirements of the U.S. Fish & Wildlife Service under the proposed designation of threatened by similarity of appearance. This proposed rule recognizes the improved status of the ranched populations and, if approved as a final rule, will allow regulated trade of live animals and whole skins as long as CITES requirements are met and the laws of Zimbabwe are followed. It will not change protection given to the wild population of *C. niloticus* in Zimbabwe and elsewhere in Africa —these are listed as endangered under the Endangered Species Act and will remain in Appendix I of CITES.

Proposed reclassification of the American alligator throughout the remainder of its range to threatened due to similarity of appearance. The U.S. Fish & Wildlife Service proposed (FEDERAL REGISTER, 2 June 1986; comment deadline 1 August 1986) to reclassify *Alligator mississippiensis* in the states of Alabama, Arkansas, Georgia, Mississippi, North Carolina, Oklahoma, and South Carolina from its present classification of endangered or threatened, to threatened due to similarity of appearance. This has already been finalized in Florida, Louisiana, and Texas. The proposed change is based on evidence that the species is no longer biologically endangered or threatened. According to the U.S. Fish & Wildlife Service, alligator populations in the seven affected states are relatively stable, reflecting improvements in management of alligators in recent years through the activities of federal agencies, states, and private groups. Reclassification would reduce restrictions on states for future management and research and would be a formal recognition by the Service that the American alligator is biologically secure throughout its range. A final rule would result in removal of federal agency responsibilities under section 7 of the Endangered Species Act. States would have the option of harvesting alligators, although any such taking will continue to be strictly regulated by the Service's special rule on all taking and commerce in American alligators and their parts, as well as by the Lacey Act which prohibits interstate commerce in illegally taken wildlife or their products. This proposed action, if implemented, would not be an irreversible commitment on the part of the Service. Relisting is possible if the status of the species changes or if states materially change their plans or actions in a way that may threaten the species.

Proposed listing of the Alabama red-bellied turtle as a federally threatened species. The U.S. Fish & Wildlife Service proposed (FEDERAL REGISTER 8 July 1986, comment deadline 8 September 1986) to list *Pseudemys alabamensis* as a threatened species under the Endangered Species Act. This species has a restricted distribution (lower Mobile River floodplain in Baldwin and Mobile Counties, Alabama) and nesting occurs in only one known area, a sand beach on a privately-owned island. The turtles' recruitment rate is declining due to human disturbances on the nesting grounds (e.g., by three-wheeled vehicles and other heavy human uses during the nesting season). The turtle has a small

- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

average clutch size (6 eggs) and specimens are being taken by headlights and dip nets for the pet trade and by trawling during winter for sale as food. Although more research is needed, federal listing of the Alabama red-bellied turtle will accomplish a coordinated effort to conserve this species not available by other means.

Proposed listing of the western population of the gopher tortoise as a federally threatened species. The U.S. Fish & Wildlife Service proposed (FEDERAL REGISTER 8 July 1986, comment deadline 8 September 1986) to list all populations of *Gopherus polyphemus* occurring in Alabama west of the Tombigbee and Mobile Rivers, in Mississippi, and in Louisiana, as threatened under the Endangered Species Act. In this portion of the species' range, the historic habitat has been reduced by more than 80% and adverse forest management practices continue to threaten the tortoises' habitat, particularly on the ca. 70% of gopher tortoise habitat held in ownership by the forest industry and by private individuals. Females take approximately 20 years to reach maturity, and the mean clutch size is small (5.8 eggs/clutch). Documented human predation rates ("gopher pulling" and taking for pets) and road mortality may already be at a level that would offset annual recruitment. Population densities have declined by an estimated 67% in Alabama and 91% in Louisiana, according to a recent survey. Existing regulatory mechanisms (listed by Mississippi as an endangered species, considered a game animal in Alabama with no open season, recently protected within DeSoto National Forest by the U.S. Forest Service, and Lacey Act prohibitions against interstate commerce) are inadequate to assure protection of the western population of *G. polyphemus*. Federal listing of the gopher tortoise will accomplish a coordinated effort among federal, state, and private agencies to conserve the western populations of this species not available by other means.

Final rulemaking: determination of the Concho water snake to be a threatened species. The U.S. Fish & Wildlife Service (FEDERAL REGISTER 3 September 1986) has determined that *Nerodia harteri paucimaculata* is a threatened species under the authority of the Endangered Species Act. A final decision on the determination of critical habitat for the Concho water snake will be published in a separate notice by January 1988. Historically, the Concho water snake occurred over about 276 river miles of the Colorado and Concho Rivers in Texas. Now, it is distributed discontinuously over a reduced range of about 199 miles in ten counties of Texas. The known populations are currently vulnerable due to low numbers and the threat of further loss of habitat from dam impoundments and downstream effects from reservoir construction. Stacy Reservoir, on the Colorado River, is an additional reservoir planned within the remaining range of the Concho water snake. This proposed impoundment would inundate 32 miles of the Colorado River and 14 miles of the Concho River, or 35% of the proposed critical habitat for the species. An extensive but unknown amount of habitat downstream from the dam could also be affected, depending on the amount and timing of water releases from the reservoir. Overall, the Service estimates that 48% of the proposed critical habitat and 76% of the individual snakes that have been located occur within the area expected to be primarily affected by the construction and operation of Stacy Reservoir, as proposed. Federal listing of the Concho water snake will solidify the efforts of SSAR and other herpetological groups, as well as federal and state agencies, to assure the preservation of this species in the Concho and Colorado Rivers in Texas.

MEETINGS

TURTLE SYMPOSIUM HELD IN VERACRUZ

On March 4-8, 1986, the third symposium of the Freshwater Turtle Ecology Group met at Estación de Biología Tropical "Los Tuxtlas" near Catemaco, Veracruz, Mexico. The meeting was coordinated by Richard C. Vogt, C. J. McCoy, and Oscar Flores Villela. Participants arrived from Brasil (1), Canada (1), Mexico (19), and USA (25). Thirty-four papers were presented along the general theme of Neotropical Freshwater Turtle Ecology in the following categories:

Ecology: Gustavo Aguirre Leon, R. Bruce Bury, J. Whitfield Gibbons, Dale Jackson, Ed Moll, Don Moll, David Morafka, Debra Moskowitz, and Salvador Morales V.
Systematics: James Berry, John Carr, John L. Iverson, Dale Jackson, John M. Legler, C. J. McCoy, Peter Meylan, Anders Rhodin, Michael Seidel, and Robert Webb.
Reproduction: James Berry, Justin Congdon, Oscar Flores Villela, and Joseph Mitchell.
Sex Determination: Ronald Brooks and Richard C. Vogt.
Genetics: John W. Bickham and Brian Hanks.
Morphology: Robert W. Winokur.
Embryology: Michael Ewert, Horacio Merchant L., Irma Villalpando, and Brulio Centerno.
Age Determination: George R. Zug.

In addition to the formal paper sessions evening informal slide presentations were held including: Turtles of Brasil, Herpetofauna of Los Tuxtlas, Turtles of India, My Favorite Turtle Shots. A field demonstration of radio telemetry used in conjunction with turtle dogs was also held in one of RCV's nearby study areas. A monograph volume is being prepared by 24 of the participants who have submitted titles.

FEATURES

IMPORTATION OF LIVE SNAKES AND SNAKE PRODUCTS INTO THE UNITED STATES, 1977-1983

During the course of preparing a review on the worldwide status of snakes (Dodd, in press), a significant amount of information on trade in both live snakes and snake parts and products into the United States, available only in unpublished or difficult to obtain U.S. government reports, was summarized. Limited space precluded publishing these data in the review, but inasmuch as the United States is a major consumer of wildlife products (King 1978) and since these data provide a valuable insight on what may be a serious threat to many species of snakes, it seemed desirable that such data be disseminated more widely than presently available.

To estimate the volume of legal trade, I summarized raw data contained in reports prepared by the Wildlife Permit Office of the U.S. Fish and Wildlife Service for the years 1977-1983. These data were assembled as part of the responsibility of the United States to monitor trade in species listed in the Appendices of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), specified by Article VIII, paragraph 6.

Commerical importation of species listed on Appendix I is generally banned, unless a reservation is taken in accordance with Article XXIII of the Convention, though such species may be imported for scientific research or other purposes by obtaining a permit issued by the importing and exporting countries. Commercial trade in Appendix II species is allowed if the exporting country issues appropriate permits, though national law may supercede the requirements of the Convention (CITES 1973).

RESULTS AND DISCUSSION

Between 1977 and 1983, 246,314 live specimens of 44 species listed on Appendices I and II were imported legally into the United States (Table 1). The vast majority were boids, which is not surprising since the entire family Boidae is listed in Appendix II. By far the most popular species was *Boa constrictor* from Central and South America. In general, the trade in most species neither increased nor decreased markedly during these years, with the exception of imports in 1979. In that year, there were very large numbers of boas *(B. constrictor)* and pythons *(Python molurus* and *P. reticulatus)* imported, making 1979 the year with the greatest total imports. After 1979, importation of these species decreased substantially.

The data on snake parts and products are difficult to assess and interpret. This is because skins may be imported or exported as pieces, finished products, or as whole skins. Sometimes shipments are recorded not in article counts, but in poundage, meter, or square meter lots. At the same time, species may or may not be correctly identified, shipments may include items produced from many different species, and species may be imported and reexported many times prior to final destination. It is not uncommon for shipping labels to indicate species being imported from locations halfway around the world from where they occur naturally.

To obtain an estimate of trade in such products, I tabulated statistics on the five most common CITES imported species, all of which were boids. These data show that a very large number of products from these species were brought legally into the United States between 1977 and 1983 (Table 2). Nearly 620,000 whole skins, 50 uncatalogued lots, 376,000 m, 17000 m^2, and 5600 kg of skins were imported during this time span. Since commercial breeding programs do not occur for any of these species, all specimens used to supply this trade must come from natural populations.

A formula for estimating how trade figures may be converted into the number of individual specimens needed to supply such trade is unknown and may be impossible to reliably develop for snakes. For instance, if one assumes the average commercial boa skin from South America to be 2.5 m (W. King, pers. comm.), then in 1983, the 89125 m of imported skins would translate into 35,650 individuals. Similarly, it would be possible to estimate how many skins would be needed to weigh one kg, or how many m^2 are found per average 2.5 m skin, and then extrapolate these figures to determine the number of individual snakes. However, it still would be difficult to obtain an overall estimate because of the lack of data on the number of skins required to manufacture each finished item. In addition, the sizes of unfinished leather goods and pieces are unknown, and many shipments contained uncatalogued lots which cannot be assessed.

The figures in Tables 1 and 2 represent legal trade since all required permits for both export and import, where necessary, were obtained prior to entry into the United States. For such importation, it is automatically

The World Congress of Herpetology announces the

FIRST WORLD CONGRESS OF HERPETOLOGY

11–19 September 1989
at the University of Kent, Canterbury (U.K.)

This international congress will be the first of a series occurring at regular intervals at venues around the world. Such a meeting will enable all persons interested in herpetology to meet and exchange information to promote the advance of knowledge and the conservation of the world's amphibians and reptiles. The congress will consist of topical symposia, poster sessions, plenary speakers, workshops, displays, excursions, and meetings of ancillary groups. Subjects and moderators of symposia will be announced well in advance so that potential participants can volunteer. The meeting will be open to all persons. Registration will begin 1 January 1988.

For further details and mail listing, write: Dr. Ian R. Swingland, World Congress of Herpetology, Rutherford College, University of Kent, Canterbury, Kent CT2 7NX, United Kingdom.

Sponsoring organizations and individuals are welcome. For further details write: Dr. Marinus S. Hoogmoed, Rijksmuseum van Natuurlijke Historie, Postbus 9517, 2300 RA Leiden, The Netherlands.

assumed that the exporting country has complied with CITES provisions by the mere issuance of a permit, unless there is substantial evidence that the export permits were not properly issued. It is readily apparent, however, that while the permits issued by some governments are technically legal, the intent of CITES as specified in Article IV, Paragraphs 2A and 3, may not be followed when export permits are issued.

CITES requires that prior to issuing an export certificate or permit for species (defined in Article I(a) to mean any species, subspecies, or geographically separate population thereof) taken commercially and listed on Appendix II, the Scientific Authority of the country involved must advise that such export "will not be detrimental to the survival of that species" (Paragraph 2A). Paragraph 3 further states "Whenever a Scientific Authority determines that the export of specimens of any such [Appendix II] species should be limited in order to maintain that species throughout its range at a level consistent with its role in the ecosystems in which it occurs and well above the level at which that species might become eligible for inclusion in Appendix I, the Scientific Authority shall advise the appropriate Management Authority of suitable measures to be taken to limit the grant of export permits for specimens of that species." Both statements imply that there should be some biological data on the status of species in trade prior to issuing export permits. In the case of many of the species in Table 1 and all of the species in Table 2, necessary biological data on which decisions can be made as to whether export may or may not adversely affect wild populations do not exist for any country.

The figures in Tables 1 and 2 also do not represent some of the more common species in trade and not listed by CITES during these years, such as the Indian rat snake, *Ptyas mucosus*. Hemley (1983) reported that for only two months in 1982, 4,849 skins and 98,006 products (direct imports) and 44,231 skins and 217,983 products (indirect imports) worth $3.2 million U.S. dollars of this one species were imported into the United States. In India, Inskipp (1981) reported that between

1971 and 1974, 118,585 raw snake skins (other than *Python*), and 1971 and 1975, 5,034,584 tanned snake skins were exported. Between 1976 and 1979, 3,075,664 individual skins plus 26,200 additional kilograms of tanned skins were exported. Most of these skins were *Ptyas* and were exported to Europe, Australia, and Japan. India has now banned commercial export of this species.

European countries and Japan (major importers), along with African, South American, and other Asian countries (major exporters), keep trade statistics of varying degrees of accuracy. Although not readily available, such statistics show high levels of trade both in the past and present. For instance, Bruno (1973) recorded 14,760 live colubrids and 51,210 viperids imported into Italy from 1968 to 1970 for commercial purposes. In India, Joseph (1982) reported illegal trade still accounts for several hundred thousand skins per year at the same time that protective legislation has significantly reduced legal trade. The level of trade worldwide in both legally and illegally traded specimens of live snakes and snake products must be enormous, but unfortunately is impossible to accurately quantify.

Until data on the biology and life histories of snake species in trade are forthcoming, the impact of commercial take on the status of species listed in CITES appendices will remain unknown. Considering that many heavily traded species, such as sea snakes, are not listed in CITES appendices, that the extent of illegal trade is certainly massive, and that the habitats of many of these snakes, particularly the larger boids, are being threatened by deforestation and other human-related activities, such trade figures are sobering and cause for concern.

ACKNOWLEDGMENTS

I thank Kevin Enge for assistance in reviewing the data and Susan Lawrence, Federal Wildlife Permit Office, for providing the unpublished 1983 U.S. CITES report. F. Wayne King and Richard Seigel provided valuable comments on the manuscript.

a. For 1982 and 1983 data, small finished items (belts, handbags, watchbands, wallets, shoes and other misc. items) were lumped together, as were large items (incl. briefcases and garments). These data are provided in the "Leather" column with the first number the number of large items, the second the number of small items.
b. Large and small items lumped for 1982 and 1983 to provide the total.

RESUSCITATION OF A COMATOSE GREEN TURTLE

Fewer sea turtles would drown from incidental capture in shrimp trawls and other fishing gear if better resuscitation procedures were used. The current recommended practice is to hold a comatose turtle out of water in either a prone or supine position, and see if it revives over a period of 1 to 24 h. The turtle's posterior should be elevated if held prone. If placed on its back, the plastron should be periodically compressed ("pumped") by hand or foot (Hopkins and Richardson 1984). The actual manner in which these manipulations may foster resuscitation has not been described. Presumably they are aimed at ventilating the lungs, draining water from the respiratory passages and lungs, and promoting cardiovascular function. It is unknown what percentage of comatose turtles are revived, or what the survival rate of revived turtles is following release. From the high frequency of beach strandings adjacent to certain shrimp trawling areas, considerable mortality apparently takes place (Shoop and Ruckdeschel 1982), although it is not known whether attempts were made to resuscitate these turtles.

The resuscitation of a comatose green turtle, *Chelonia mydas*, at Johnston Atoll (lat. 16° 45'N, long. 169° 31'W) in November of 1983 provided a new perspective on the problem, and suggested the use of additional therapy. During a tagging study employing large mesh nets in algal foraging pastures, an entangled subadult green turtle (68 kg, 76 cm carapace length) became snagged on coral 2 m deep making it unable to surface. The seawater temperature was 27.5° C. The turtle was submerged for at least 30 min before emergency retrieval could be carried out from a small boat. When it was brought to the surface there were no signs of life except for contraction of the tail when extended manually. The turtle was placed on its back and the plastron pumped every 2-3 min for 1 h following rescue, but no resuscitation was evident. Upon close examination, it was determined that the movement of air caused by pressing on the plastron was only taking place into and out of the esophagus, and not the trachea. At all times the glottis, a longitudinal slit posterior to the tongue, remained tightly shut and

SNAKES: ECOLOGY AND EVOLUTIONARY BIOLOGY

Edited by

Richard A. Seigel, Savannah River Ecology Laboratory,
Joseph T. Collins, Museum of Natural History, University of Kansas,
Susan S. Novak, Savannah River Ecology Laboratory

In ecological and evolutionary research, snakes occupy a unique niche. Studies of their adaptations and life histories have broad implications for the most basic questions of biology. Although their secretive and sometimes venomous nature has discouraged research, recent methodological and conceptual breakthroughs have led to a large but unreviewed literature available only to specialists.

Snakes fills the need for an up-to-date text/reference on the growing field of snake ecology and evolutionary biology. Here, in one volume, is an extensive review of the biology of these fascinating reptiles, including such topics as zoogeography, fossil history, systematics, foraging, and reproduction. With contributions from many leading herpetologists, this work is divided into sections on *Systematics and Morphology, Techniques,* and *Life History and Ecology.* Each section summarizes what is known about these major fields of snake biology and synthesizes the primary literature, both for the experienced investigator overwhelmed by the mass of citations available and for the student just starting to study snakes.

Snakes will well serve the needs of those actively involved in research and will stimulate new and innovative herpetological research. The biological community—the experienced researcher, the amateur naturalist, and the beginning student—will find *Snakes* invaluable.

could only be opened by forcing a finger into it. When the finger was withdrawn, the glottis immediately returned to the closed position. To hold the glottis open and permit the passage of air, a 40-cm piece of 10 mm outside diameter, 7 mm inside diameter, plastic tube was inserted 2 cm. With the turtle prone, the lungs were then ventilated by gently blowing into the tube at irregular intervals over the next hour. No water drained out through the tube, although fluid apparently from the stomach came out of the mouth. After being seemingly lifeless for over 2 h, the turtle suddenly raised its head well into the air and took a deep breath. For the next 30 min distinct breaths gradually became more frequent and the tube was finally removed. Movement of the flippers also gradually resumed. The turtle was left prone for the next 11 h in a confined area. In the morning it was found active and appeared fully recovered. A large quantity (1.5 kg) of voided feces was present. When released, the turtle swam a short distance near the surface, took a breath, and dove out of sight in a normal manner.

Dead green turtles of various sizes which I have examined have all shown a closed glottis, like the comatose specimen reported here. This appears to be the normal state, serving to prevent the inhalation of seawater. The glottis appears to open only with the outward movement of the hyoid apparatus and gaping of the mouth to take a breath. Closure of the glottis in the green turtle, or any other sea turtle species, has not been previously mentioned in connection with resuscitation efforts. If the goal is to ventilate the lungs, then an open air passage must be established. The insertion of a small plastic tube is a simple and convenient way to meet this objective. In addition, since the lungs are located dorsally, under the carapace, the prone position for resuscitation would seem best to avoid compression from the heavy food-laden digestive tract and other organs.

OBSERVATIONS ON LIVE *Azemiops feae*, FEA'S VIPER

Rare and poorly known even within its natural range of southern China and adjacent southeast Asia, *Azemiops feae* nevertheless occupies a strategic phylogenetic position within advanced snakes. The first specimen collected was in Burma by the European explorer M. L. Fea. This find was reported by Boulenger in 1888, who named the monotypic species in honor of Fea and allied the snake with *Atractaspis* and *Causus*. However, the most recent attempt to establish its phylogenetic relationship (Liem et al. 1971) concludes that *Azemiops* is a distant, but primitive evolutionary line within the Viperidae. Character comparison places it between the genera *Causus* on the one hand and *Agkistrodon* on the other (Marx and Rabb 1972). The implication that *Azemiops* was an early offshoot of the mainline of vipers gives it an important position within the radiation of viperids.

In China, *Azemiops* has been reported in the southern provinces—Yunnan, Guizhou, Sichuan, Guangxi, Fujian, Jiangxi, and Zhejiang (Zhao and Zhao 1981). To this range is added, of course, Burma (Boulenger 1888) and preserved specimens in the Museum National D'Histoire Naturelle (Paris) with collection locations of North Viet Nam and Tibet. To summarize Zhao and Zhao (1981), this species is montane (100-2000 m in altitude), seasonal (active 7 March to 24 November), and crepuscular; it is found at roadsides, along rice fields, in straw or grass, and even beside or within homes.

Over the last several years, we obtained living specimens from China that arrived in the United States in November. The actual field collectors have not released details, but the snakes were presumably caught in the wild shortly before shipment when the snakes would be preparing for hibernation. Observations of these living snakes, supplemented by preserved specimens, give a clarified picture of these very primitive vipers.

Azemiops feae goes by several common names: Fea's viper (after its discoverer), jade-belt snake (reference presumably to the broken ring pattern along its body), and white-headed viper (actually a misleading name). In life, the head of *Azemiops* is burnt orange to yellow, with a symmetrical pattern of dark rust colored spots. When preserved, this head color bleaches to white, the presumed source of its latter common name. The tongue is banded. The body is gray black. Beginning at the neck, the body is crossed by orange rings, one or two scales wide. These rings are often disconnected dorsally so that each side is slightly offset (Fig. 1). The rings do not continue across the belly. The belly is evenly cream colored with a slight pinkish tinge. Two (2) of fifteen (15) individuals had bobtails, cleanly healed, likely the result of a natural injury.

When threatened, all displayed a distinctive defensive behavior. Characteristically the body would be flattened and thus laterally widened; the usually oval head was reconfigured into more of a triangular shape by outward flaring of the back of the jaws (quadratomandibular joints). Some vibrated their tails rapidly. If intimidated at close range the snake would strike toward the threatening object with mouth open, sometimes erecting, other times not erecting the fangs. One vigorous strike reached over 18 cm in a snake 63 cm in total length. The disturbed *Azemiops* sought cover (e.g. hidebox) when available, or escape.

The only report of stomach contents is of a common gray shrew (Marx and Olechowski 1970). In captivity, we found all generally reluctant to feed. Those that did, usually ate (newborn mice) unseen overnight. The three observed predatory strikes were newborn

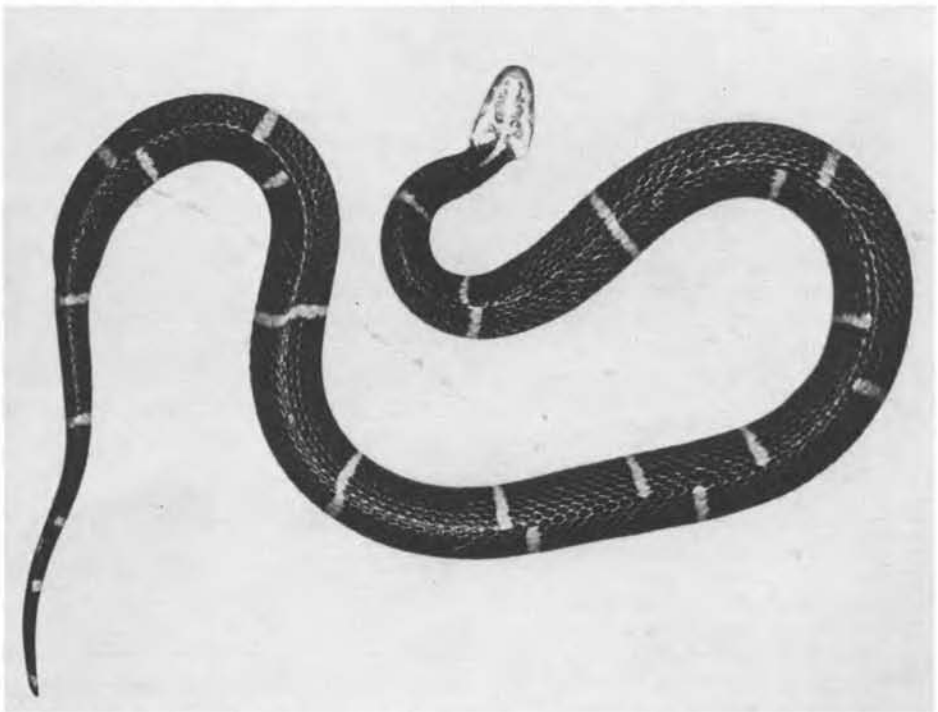

Figure 1. *Azemiops feae*, Fea's viper. In life the head is orange to golden with dark brown mottling or spots symmetrically placed. The body is gray-black, crossed by orange rings that may be continuous (e.g. first and third rings in neck) or broken (e.g. second and fourth rings). The pictured individual, a male, was 45.4/9.1 cm snout-vent/tail length respectively.

mice which were not released but held in the jaws. None showed an interest in small amphibians (*Rana pipiens, Ambystoma macrodactylum*), fish (guppies), or lizards (*Anolis*) although this could reflect a general loss of appetite prior to hibernation.

All live *Azemiops* were kept individually or in pairs in terraria with 2-3 cm of potting soil on the bottom, temperature gradients (15-33° C), hide boxes, and loose cover (paper). The light cycle was 12L/12D upon arrival but two weeks later reduced to 8L/16D I. Water was available ad libitum. Although they would push at the potting soil with their snouts, no burrowing activity was observed. Hide boxes within the cooler temperatures were preferred (15-20° C). Despite the continuous presence of water in shallow dishes, and observed occasional drinking, the snakes seemed especially susceptible to dehydration as evidenced by weight loss (up to 10% in 30 days in some).

Within five weeks of their arrival, histological examination (H & E, light microscopy) of the left ovaries of two females revealed three and five ovarian follicles, the largest approximately 1.5 x 8 mm. Neither ovaries nor reproductive tracts suggested oviparity or viviparity. One testis from each of five males was similarly examined. In all the males, the seminiferous tubules were up to three cell layers thick, lumina were conspicuous, and stages up to advanced spermatids and spermatozoa were present, although neither were numerous.

ACKNOWLEDGMENTS

For care and concern over these snakes, thanks to Charles Leathers, Alison Archambault, and Darwin Vest. The following museums (and curators) generously shared valuable specimens with me and I extend sincere thanks to: Field Museum of Natural History (H. Marx), National Museum of Natural History (W. Ronald Heyer, Ronald I. Crombie), and Museum National D'Histoire Naturelle (J. Guibé).

METHOXYFLURANE ANESTHESIA IN *Crotalus:* COMPARISONS WITH OTHER GAS ANESTHETICS

Each anesthetic technique has its advantages and limitations. Most have been reported in veterinary journals, rather than in herpetological publications, and are unfamiliar to many herpetologists. Because of their veterinary orientation, most of these publications assume familiarity with anesthetic agents and access to gas anesthesia machines. This paper combines my observations on inhalation anesthetics in rattlesnakes with published studies and technical information on these agents. It is hoped that increased familiarity with anesthesia will promote nondestructive research methods in herpetology wherever feasible.

Three types of anesthesia have been employed with reptiles. Cold-induced narcosis is perhaps the oldest technique, but also the

ELECTRONIC MONITORING of REPTILES and AMPHIBIANS

For more than 16 years, Wildlife Materials technicians have helped biologists preserve threatened and endangered species. We adapt our telemetry systems to the habitat, behavior and body shape of any aquatic animal. Snakes, for instance, wear thin, light-weight implantable transmitters, while crocodiles and turtles carry a tracking device mounted on their backs or riveted to the scutes.

Electronic monitoring provides researchers with scientific samplings that
—identify habitat use and requirements
—register temperature to determine health and ovulation
—record behavior, from rest to slow movement to rapid action

An efficient telemetry system consists of a beeping, subminiature **transmitter**, waterproofed with beeswax and acrylic; a state-of-the-art **TRX-1000S Receiver**, which tracks up to 200 different frequencies simultaneously and which has a sophisticated noise-blanking circuit; a three-element folding directional **antenna** for signal reception over long distances and a loop **antenna** for picking up signals in a close, confined area.

least useful, because restraint is generally short-lived. In addition, Northcutt and Butler (1974) reported necrotic changes in brain from such treatment. Injectable anesthetics have the disadvantage of dose-dependency. That is, it is necessary to know the weight of the snake before administering the anesthetic. Use of injectable agents is complicated by the fact that mammalian and avian doses are unpredictable in reptiles (Sedgwick 1980). Great differences in responses of different taxa to the same anesthetic have also been reported (Brazenor and Kaye 1953; Betz 1962). Thus one must have considerable experience with both the species and the anesthetic in question. For instance, Glenn et al. (1972) reported that the mass-proportional dose (mg/kg) of Ketamine HCl required to attain a given plane of anesthesia varies with the mass of the snake, large snakes requiring larger mass-proportional doses. Such variability presumably exists for other anesthetics. Because injectable anesthetics are usually processed by the liver and kidneys, toxicity problems may arise, particularly if there is pre-existing liver or kidney dysfunction. Lastly, injectable agents necessitate handling of unanesthetized specimens, which is precisely what some users of anesthetics wish to avoid.

In contrast to injectable agents, inhalable anesthetics are simple to use because they do not require calculation of mass-proportional doses. Depth of anesthesia may be judged by such criteria as loss of the righting reflex, absence of the tongue-withdrawal reflex, failure to respond to a tail pinch, and gradual loss of muscle tone. These agents may be administered in any closed cage or container with a transparent side, obviating handling of specimens prior to anesthesia. Since inhalable anesthetics are expelled primarily through the lungs, anesthesia may be readily reversed by tracheal intubation. Gas anesthetics injected i.p. in rats are metabolized at levels of 1.5-10% (Chenoweth 1965).

Four substances have been used as inhalable anesthetics: diethyl ether, chloroform, halothane, and methoxyflurane. Ether is undesirable because of its explosive nature. It is also ineffective against crotalid snakes. An adult *Crotalus v. viridis* that I placed in a concentrated ether atmosphere showed no signs of anesthesia after over two hours. Sedgwick (1980) reported similar difficulties. Chloroform may be used as an inexpensive terminal anesthetic for some applications, but is not generally recommended. Lumb and Jones (1984) report that chloroform is directly cardiotoxic, and that it decreases liver and kidney function. It may also act directly on blood vessel musculature as a vasodilator. The resultant drop in blood pressure can produce shock. Chloroform is also known to be hepatotoxic in humans and is suspected as a carcinogen; thus, its use involves safety hazards.

Despite their high potency (4x and 8x that of ether, respectively), halothane and methoxyflurane are both non-irritating to respiratory tissues, and have been recommended for reptilian anesthesia (Hackenbrock and Finster 1963; Gandal 1968). Nonetheless, they affect snakes quite differently. Despite the attractiveness of halothane's price and shorter induction time, it causes high mortality if anesthetic concentrations are not regulated with a gas anesthesia machine. Differences between the two agents will be discussed hereafter, along with a possible explanation for halothane's lethality.

METHODS

The principal advantages of methoxyflurane are its simplicity and consistency. Dosage is determined by duration of exposure to the anesthetic, not the volume employed, provided that concentrations adequate for induction are achieved. A wide-mouth, one-gallon mayonnaise jar or a closed, glass-fronted cage will suffice. Several mls of anesthetic are poured onto an absorbent in the container bottom and the specimen's behavior is observed to determine the initial depth of anesthesia. Snakes usually become hyperactive within one to three minutes after exposure to the anesthetic. This resembles an accelerated "searching" behavior. Although some specimens become somewhat violent, no injuries have been observed. This hyperactive phase is followed by an abrupt depression of activity. Complete inactivity occurs in *Crotalus* in 5-15 minutes. As the depth of anesthesia increases, specimens next lose their righting reflex. This is easily determined by turning the jar or cage. Respiration diminishes more or less concurrently with the righting reflex. Cessation of respiration is due to progressive paralysis of the skeletal musculature. When the tail-pinch reflex disappears the animal may be safely removed from the anesthetic. Most *Crotalus* require 15-25 minutes to reach this stage. Most snakes lose control of the posterior trunk and tail near the time respiration ceases and they regain control of these portions of the body first during re-emergence. After respiration stops, muscle tone gradually vanishes until the animal becomes flaccid. Ideally, anesthesia should be no deeper than that required by the procedure to be performed, to shorten recovery time. For major surgical procedures or extended morphological studies, the flaccid state is desirable, although respiration should be assisted during the procedure to mitigate acidosis. Anyone who has attempted measurements of body length on well-preserved large snakes will appreciate the ease and accuracy of this approach.

The snake's anesthetic plane may be determined by noting muscle tone. Oxygenation can be monitored by the color of oral mucous membranes. If the mouth begins to lose its normal pink color, a fire-polished glass tube is inserted into the glottis and the animal is inflated (to normal volume) by mouth and deflated by hand several times. This should be done every 5-10 minutes. Normal coloration returns immediately. At the end of surgical procedures or other manipulations of the animal, it should be ventilated until it is able to breathe on its own for ten or fifteen minutes.

DISCUSSION

Animals anesthetized with methoxyflurane emerge from anesthesia quite predictably. Muscle tone returns gradually and when activity resumes, it is subdued. With halothane, emergence is not predictable. On one occasion, I was making dorsal scale row counts on a large rattlesnake, when it suddenly surged forward, looking about and actively flicking its tongue. There had been no indication that recovery was imminent. This was not an isolated incident. Relapses following initial recovery are common with inhalable anesthetics. These have been attributed to warm temperatures or excessive activity during recovery, so that oxygen demand exceeds delivery capability (Brazenor and Kaye 1953).

Mortality of snakes associated with methoxyflurane has been reported only once. Burke and Wall (1970) attributed deaths of two *Naja* and one *Ophiophagus* to this anesthetic. I have had only two fatalities, despite over 150 uses on rattlesnakes and kingsnakes. Both were rattlesnakes that had been force-fed heavily under anesthesia. Neither was breathing when left to recover overnight and neither was manually ventilated to assist recovery. This was also true of the three cobras discussed by Burke and Wall (1970). Elapids may be hypersensitive to this agent, as has been reported for halothane (C. Gans, cited by Burke and Wall 1970); however, I suspect that the absence of any post-anesthetic care was the principal cause of the elapid deaths.

By contrast, halothane causes high mortality in *Crotalus* without careful regulation of anesthetic concentrations. Fatalities have also been reported in most domestic animals and in pronghorn antelope. This may be explained in part by the physical properties of halothane. A concentration of 2-4% is generally employed for induction, followed by a maintenance concentration of 0.8-1.2% (Lumb and Jones 1984). At 20° C, however, halothane vaporizes to about 32%, roughly 10-fold higher than the proper induction level and 40 times higher than safe maintenance levels. By contrast, methoxyflurane, which requires comparable induction concentrations, vaporizes to only 3.5%. This makes initial overdosing difficult.

Snakes that fail to emerge from halothane anesthesia suffer massive pulmonary edema. Five to ten mls of plasma may be poured out of such snakes (80-100 cm long). In reptiles pulmonary arterial pressures are similar to systemic arterial pressures (Burggren 1977, 1982) and may exceed mammalian values by 5-fold. Colloid osmotic pressure, which counterbalances plasma filtration into non-vascular spaces, is lower in reptiles than in mammals. Blood plasma loss is 10 to 20-fold greater in turtle lungs than in mammalian lungs. Whether this fluid is identical to blood plasma drawn directly from blood vessels is not known. Vessel walls present a partial barrier to blood proteins, but reptilian blood vessels are evidently less able to restrict protein leakage than those of mammals (W. W. Burggren pers. comm.). In *Chrysemys scripta* net plasma loss amounts to 20-30% (Burggren 1982). Preliminary observations suggest that snake arterial pressures and pulmonary "leakiness" are similar to those in *Chrysemys* (W. W. Burggren pers. comm.). Lumb and Jones (1984) report that halothane produces hypotension amounting to a decline of 20-40 mm Hg in dogs. Burggren (pers. comm.) has observed increased blood pressure in reptiles anesthetized with halothane, and it seems likely that increased blood viscosity resulting from plasma loss accounts for the hyperten-

sion in reptiles.

Whether pulmonary plasma loss was the sole cause of the rattlesnake deaths I observed is not clear. Halothane apparently acts upon the vagus nerve to cause bradycardia (Lumb and Jones 1984), which increases with the depth of anesthesia. Deutsch (1971) reported that halothane causes direct myocardial depression. Halothane also sensitizes the myocardium to arrhythmias induced by catecholamines. It is possible that increased blood viscosity resulting from pulmonary plasma leakage exacerbates halothane-induced bradycardia to cause cardiac arrest. Whether halothane acts directly on pulmonary blood vessels to increase their plasma permeability is not clear, but given the lengths of time that snakes can be anesthetized without breathing, cardiac failure seems a more likely cause of death than fluid interference with oxygen transfer.

The methoxyflurane procedure outlined above has also been successfully employed for obtaining liver biopsies from sceloporine lizards (P. Thompson and J. W. Sites pers. comm.). After recovery from surgery these lizards were marked and released at their capture localities. Preliminary recapture data did not indicate increased mortality resulting from the anesthesia-biopsy procedure.

Animals should not be released until well recovered from anesthesia because of possible relapses and because of temporary residual effects that might result in increased predation. Residual effects are possible, in part, because of methoxyflurane's high fat solubility. It is exhaled by mammals in detectable quantities up to 48 hours post-surgery (Lumb and Jones 1984).

In contrast to ether, chloroform and halothane, methoxyflurane appears safe and effective for squamate reptiles, even under conditions where anesthetic concentrations are not controlled. It is especially safe when specimens are manually ventilated to accelerate their recovery.

ACKNOWLEDGMENTS

I thank Dr. Richard Broadstone of the Colorado State University Veterinary School for his consultation early in this project, and Dr. Elizabeth S. Williams of the Wyoming State Veterinary Research Laboratory for reviewing the manuscript. I also thank Dr. Martin J. Rosenberg and anonymous reviewers for their constructive criticism.

ANOMALOUS RECORDS OF THE OCCURRENCE OF *Paleosuchus trigonatus*

It has generally been considered that the distributions of *Paleosuchus trigonatus* and *P. palpebrosus* are largely coincident or that *P. trigonatus* occupies an "inner circle" and *P. palpebrosus* extends further on the perimeter of the distribution (Medem 1967, 1983). In sympatric areas one species is usually common and the other rare (Medem 1967, 1981, 1983). Surveys are lacking for many areas but the general distributions can be obtained by linking the peripheral localities given by Medem (1983) in a minimum convex polygon similar to that used in home range studies (Rose 1982). To avoid including large areas on the periphery that contained no records we included the condition that points should be joined only if separated by less than 1000 km (Fig. 1).

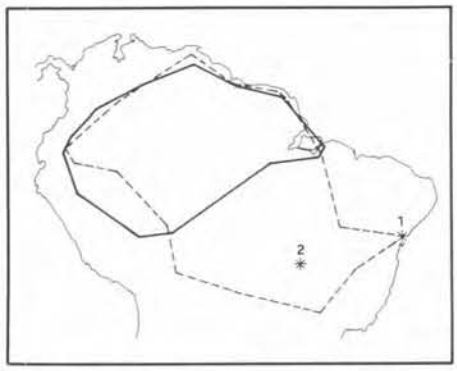

Figure 1. General distributions of *Paleosuchus trigonatus*, solid line; and *P. palpebrosus*, broken line. Asterisks represent anomalous outlying localities for *P. trigonatus*.

The two species are obviously largely sympatric over the Amazon basin, the southern part of the Orinoco basin and the coast between. However, with two exceptions, all localities south of the Amazon basin on the high plains of the Brazilian shield or on the coast are of *P. palpebrosus*. It is those two exceptions which will be discussed here.

The localities "Ciudad de Bahia" (Fig. 1, "1") and "Aruanã" (Fig. 1, "2") given by Medem (1983) are 1300 km apart and are 1300 and 1400 km, respectively, from the closest locality records for *P. trigonatus*. Neither locality supports the dense tropical forest with small blackwater streams which is typical of the greater part of the range of *P. trigonatus*.

"Ciudad de Bahia" (= Salvador) has been questioned as a locality for *P. trigonatus* before (Hoogmoed and Gruber 1983). Spix (1825) described *Jacaretinga moschifer* from "Ciudad de Bahia." Vaillant (1898) considered *Jacaretinga moschifer* to be a composite, the description based on *P. palpebrosus* but the figure based on *P. trigonatus*. Medem (1967, 1983) considered the figure to be based on *P. trigonatus* and so synonimized *J. moschifer* with *P. trigonatus*. Other localities nearby have *P. palpebrosus* and Medem (1967) considered it highly unlikely that the exact location at which Spix collected still supports crocodilians as it now forms part of the city of Salvador. We agree with Vaillant (1898) and Hoogmoed and Gruber (1983) that Spix's explicit mention of four rows of dorsal scutes between the hind legs indicates that *J. moschifer* is based on a *P. palpebrosus*. A confusing drawing is not sufficient evidence to consider that this locality is valid for *P. trigonatus*.

The locality record of Aruanã is based on a skull labelled "Aruanã" seen by Medem in the Parque Educativo Goiânia, in October 1973 (Medem 1983:159). One of us (MY) visited the Parque Educativo Goiânia (a zoo) in February 1985 and attempted to locate the skull. The director of the zoo said that all skulls exhibited at the zoo had been prepared by Prof. José Hidasi and that the material had been returned to him. Prof. Hidasi was unable to locate the skull in his collection and thought he may have donated it to someone. However, he said that material in his collection labelled Aruanã had come through the port of Aruanã but was not necessarily col-

lected there. Prof. Hidasi provided the following statement in a letter dated 30 August 1985 (translation from original in Portuguese):

> Attending the request of our colleague Dra. Megumi Yamakoshi I give my opinion about a skull of *Paleosuchus trigonatus*, mentioned in the book by Dr. Frederico Medem, entitled "Crocodilos da Amèrica do Sul."
>
> After examining our collections, I come to the conclusion that the skull mentioned possibly entered through the Port of Aruanã, as happened with many other animals and not that it was collected in Aruanã. It could have arrived there as easily from the Pantanal of Mato Grosso, as from regions of Belém-Pará.

The Pantanal of Mato Grosso represents the southernmost limit of the distribution of *Paleosuchus palpebrosus* and the region of Belém, Pará has many confirmed localities of *P. trigonatus* (Medem, 1983:158). Obviously the meaning of "Aruanã" on the label seen by Medem is too imprecise to be of any zoogeographic relevance. It is unfortunate that Dr. Medem did not meet Prof. Hidasi when he was in Goiânia.

We hope that much more collecting of crocodilians will be done on the high plains of the Brazilian shield and the area around Salvador, but until some evidence is obtained, zoogeographic hypotheses should be based on the assumption that *P. trigonatus* does not occur there.

RITUALIZED COMBAT IN CAPTIVE DUMERIL'S MONITORS, *Varanus dumerili*

Ritualized combat has been reported in several species of varanids [*Varanus bengalensis* (Auffenberg 1981; Deraniyagala 1957), *V. salvator* (Honegger and Heusser 1969; Vogel 1979), *V. gilleni* (Murphy and Mitchell 1974; Carpenter et al. 1976), *V. giganteus* (Waite 1929)]. No accounts of ritualized combat in *V. dumerili* have been reported. This paper identifies the behavioral acts involved in male combat behavior of *V. dumerili* and describes the sequence of acts in typical encounters. Comparisons are made between the agonistic behavior of *V. dumerili* and that of other species of varanids.

Three males were acquired on 24 March 1982 and were initially housed together in a 1.9 m long cattle tank. One of the males died on 12 June 1983. An additional male and a female were acquired on 2 April 1983 and were housed separately in 93 cm long fiberglass Ranger cages. Measurements for the individuals involved in the observations are provided in Table 1.

The exhibit cage in which the behavioral observations were made measures 1.6 m x 1.6 m x 2.4 m high with a 137 cm x 150 cm glass front. A pool occupies ca. two-thirds of the floor with a simulated river bank on the sides and back ranging in height from 40 to 57 cm and in width from 25 to 53 cm. Tree limbs anchored at the rear extend to a height of 150 cm at the front of the exhibit, where two 250 watt infrared heat lamps provide a temperature of about 36° C on the perches during the day. The air temperature in the exhibit ranges from 25 to 29° C. Fluorescent bulbs provide light from 0600-1630 h, which is supplemented by light from skylights.

Table 1. Length and mass of *Varanus dumerili* involved in the behavioral observations.

Sex/No.	SVL (cm)	Total L (cm)	Mass (gm)
Male 1	44.5	105.0	1625
2	38.5	92.5	1260
3	42.0	91.8	1350
Female	40.0	89.2	1025

On 4 August 1983, the three males and the female were transferred to the exhibit. On 2 September 1983, male 2 was removed and on 6 September, the two remaining males were observed in agonistic behavior including a combat embrace. Male 3 was removed from the exhibit and housed separately, and thereafter all males were kept individually either on exhibit or in cattle tanks. The female remained in the exhibit cage during the entire period. Observations were made when a male was introduced to the female and an already present "resident" male or when two males were introduced to the female. The initial observation was not documented, but ten staged introductions were recorded in written form, supplemented by photographs and audio and video tape recordings. The introductions took place between 21 September 1983 and 17 November 1983. Observation periods averaged 13 minutes (4 to 35) and were terminated by the removal of one of the males when action waned or when there was concern for the health of one or both of the animals.

BEHAVIORAL INVENTORY

TONGUE FLICKING: rapid extension and retraction of the tongue
HEAD JERKING: rapid spasmodic lateral movement of the head
PROBING: pushing or nudging the other lizard with the snout
CLAWING: raking the dorsum of the other lizard with the claws of the forelimbs
INFLATING: dorso-ventral expansion of the body, increasing profile
TOPPING: climbing on top of the other lizard, either partially with the fore part of the body, or completely with the entire body
BITING: gripping with the teeth
TAIL TIP WAG: lateral movement of the tail tip
FLATTENING: dorso-ventral flattening of the body and pressing against the substrate, reducing profile. Eyes are sometimes closed
BOTTOMING: pushing under the other lizard's body, with head under vent and pelvic region under head
RETREAT: purposeful movement away from the other lizard
COMBAT EMBRACE: ventro-ventral clutching with forelimbs gripping other lizard's body. This can occur while both maintain a bipedal stance, or while lying on the substrate side by side or with one atop the other
SNOUT THRUST: pushing the opponent's throat while engaged in combat embrace
HEAD CROSSING: switching head from one shoulder of opponent to the other, performed repeatedly and simultaneously by both lizards

The following sequences of events in aggressive encounters were subjectively determined from the observations.

A male is placed in the exhibit with the female and another male. One of the males begins TONGUE FLICKING and HEAD JERKING and as he approaches the other male, the HEAD JERKING becomes more vigorous. He moves toward the posterior of his opponent, TONGUE FLICKING against the pelvic area, and then PROBES and/or BITES him on the legs or flank. These aggressive behaviors are usually accompanied by INFLATION and CLAWING of the dorsum by the aggressor. The aggressor then begins TOPPING with the other lizard twisting toward him and gripping him. They then rise up into a bipedal COMBAT EMBRACE (Fig. 1). While in the bipedal stance, both lizards push with the upper torso and employ HEAD CROSSING and SNOUT THRUSTING apparently in attempts to throw the other off balance. After a period of a few seconds to half a minute, one succeeds in toppling the other and both fall to the substrate, either side by side or with one in the superior position. They may regain the bipedal stance while still in the embrace, or

break apart and initiate another COMBAT EMBRACE. COMBAT EMBRACES occur repeatedly until one of the males tires and retreats. He may be followed by the other male with TOPPING and/or BITING. The animal in the inferior position FLATTENS, accompanied by TAIL TIP WAGGING. The sequence of retreat and pursuit may continue until one male is removed. In four of the ten staged encounters, both males exhibited aggressive behavior following the sequence above and escalated into combat embraces. In introductions where no ritualized combat was observed, one male typically reacted submissively at the onset and the interaction consisted of the dominant harassing the subordinate with TOPPING, CLAWING and BITING. The subordinate FLATTENED and TAIL TIP WAGGED while trying to escape.

Biting occurred in all of the introductions and on three occasions minor lacerations resulted. In two of the trials, the lizards had to be separated because it seemed that no resolution was developing and serious injuries were likely to occur.

Dominant and submissive lizards could generally be identified from the outset of an introduction and dominance did not clearly correlate with residency. In the six introductions involving a resident, the introduced animal was dominant twice. Size also did not appear to effect dominance. The mass difference between specimens 1 and 2 was substantial (Table 1) and yet the latter dominated in three of seven introductions. Dominance shifts occurred between males 1 and 2 over the course of the introductions but these shifts did not appear to be the result of a development within an interaction.

Although the female was in the exhibit with the males, no courtship behavior was observed. In one of the introductions, a male exhibited pelvic tonguing and subsequent topping of the female, but then continued to follow the introduced male he had been chasing. On another occasion, a male approached the female while excitedly pursuing the other male. The female reacted by flattening and defecating. The male then bit her, she retreated, and he resumed his pursuit. The female showed no interest in the males during or after any of the introductions.

SALE OF *HERPETOLOGICA* BACK ISSUES

The Herpetologists' League is having a one time, limited sale of the back issues of *Herpetologica*.

Figure 1. Two male *Varanus dumerili* engaged in a combat embrace while in a bipedal stance.

Ritualized combat involving a combat embrace has been reported in several species of varanids. Bipedal combat as seen in *V. dumerili* was described for *V. bengalensis* (Auffenberg 1981; Deraniyagala 1957), *V. salvator* (Honegger and Heusser 1969; Vogel 1979), and *V. giganteus* (Waite 1929). *Varanus gilleni* did not exhibit the bipedal stance, but instead engaged in a tetrapodal configuration during combat (Murphy and Mitchell 1974; Carpenter et al. 1976). Body arching while in a lateral embrace was seen in *V. gilleni* (Murphy and Mitchell 1974; Carpenter et al. 1976), *V. bengalensis* (Deraniyagala 1957; Auffenberg 1981) and *V. salvator* (Vogel 1979). Body arching was not observed in *V. dumerili*. The only behaviors observed in the present study not mentioned in previous reports were head crossing and bottoming. Head crossing was seen in all introductions in which bipedal combat embraces were observed. Bottoming occurred several times, but was only exhibited by male 2, and may have been an individual peculiarity.

Auffenberg (1981) suggests that the purpose of ritualized combat in varanids is to demonstrate superior strength by forcing the opponent's body down to the substrate, thus establishing dominance without inflicting injury. In addition, it appears that in most varanids, ritualized combat occurs between lizards which are nearly equal in size (Murphy and Mitchell 1974; Deraniyagala 1957), when fighting would most likely be prolonged and thus result in injuries. It is not surprising that when the males are well matched, combat is recurrent and dominance shifts occur (Auffenberg 1981; Murphy and Mitchell 1974).

The occurrence of damaging bites in *Varanus dumerili* seems to contradict the theory that ritualized combat reduces the chance of injury. However, it is quite probable that the serious biting resulted from an inability of the submissive animal to escape. When opponents were involved in vigorous combat, biting was nearly absent and the goal appeared to be to establish dominance by toppling an opponent and landing on top.

The motivation for male-male combat in *V. dumerili* is difficult to determine. In other varanids, access to females appears to be stimulus for male combat behavior but it does not seem to be a major determinant of reproductive success (Auffenberg 1981; Murphy and Mitchell 1974). In the present study and in the work of Murphy and Mitchell (1974), territorial defense did not appear to be the motivation for combat. Clearly, field studies are needed to determine why male varanids engage in ritualized combat.

ACKNOWLEDGMENTS

We would like to thank the staff of the National Zoological Park's Department of Herpetology for assistance with this study, and especially the curator, Dr. Dale L. Marcellini for reviewing the manuscript. We are also grateful for the typing done by Susan Lynch and Laurie Bingaman.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

ANESTHESIA OF SNAKES *(Pituophis melanoleucus* and *Python regius)* FED ETHER-KILLED RATS

It is preferable to feed captive snakes prekilled, rather than live, adult mice and rats. Live rodents are capable of injuring the snakes during the capture and killing of the prey (Kauffeld 1969). Rodents may be killed, stored frozen, and then thawed for use as snake food. I have found it expedient to use ether to kill large numbers of rodents for snake food. After etherizing, rodents are exposed to the air for several minutes before freezing in order to allow remaining traces of ether to vaporize. Snakes in my collection readily accepted these rodents, and I have used this method for eight years with no apparent problems.

On 20 September 1984, I was given several frozen rats for use as snake food. Two of these were thawed to feed a 152 cm *Pituophis melanoleucus sayi* (captive for 2.5 yr) and a 95 cm *Python regius* (captive for 1.5 yr). The thawed rats had a strong odor of ether, so they were not fed to the snakes until the fumes had dissipated. Both snakes readily ate the rats, the *Pituophis* at 1900 h, 23 September 1984, and the *Python* at 1000 h, 24 September. The rats had been thawed on the same days they were fed to the snakes.

The snakes, kept in cages at 27° C, were not disturbed for ca. 24 hr after feeding. When they were examined, both initially appeared dead. Heartbeats were eventually detected, and after extensive handling the snakes very slowly extended their tongues. Their breathing rates were slow but were not measured. Although the snakes appeared to be on a deep plane of anesthesia, both blocked attempts to force regurgitation by forming a kink in their bodies anterior to the food mass.

The snakes were comatose for approximately 60 h after feeding. They then began crawling with difficulty in response to manipulation. Neither snake responded to movements around their heads, nor did they respond to touches on their heads. Their pupils did contract in response to bright light. The snakes appeared fully recovered ca. 72 hr after feeding.

Evidently some ether remained on or in the rats fed to the snakes. Because the rats were not used until the ether fumes were undetectable, they likely had been killed with an excessive amount of the anesthetic, and had taken some into their digestive or respiratory tracts, where it could not vaporize. Although neither snake was permanently harmed by the experience, a fatal overdose could easily have occurred. To avoid this problem, I urge others to avoid using ether to kill food animals, or to lightly anesthetize them prior to killing by another method (e.g., dislocation of cervical vertebrae). Frozen and thawed food animals with a detectable ether odor should not be used to feed snakes.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, USA.

ANURA

DENDROBATES AURATUS (Poison Arrow Frog). **PREDATION.** On 23 February 1986, at 0845 h, on a small beach of River Dantas (called Nairi by the local Indian population), at the upper, northern border of the Barbilla Biological Reserve, el. 200 m, the senior author observed a *D. auratus* jumping into the river and attempting to swim upstream. In a few seconds, the frog was captured and swallowed whole by a young, ca. 20-25 cm long "machaca" or *Brycon guatemalensis* (Characidae), a common fish in this river.

B. guatemalensis is known to feed on fruits of *Ficus* spp. and others, which fall into the water from nearby trees (Hedstrom unpubl.). The same fruits have been found in *B. guatemalensis*, which in spite of its five rows of rather sharp teeth, and apparently aggressive behavior is not known to be carnivorous (W. Bussing, pers. comm.). Perhaps the fish mistook the frog for a fallen fruit.

Poison arrow frogs are bad swimmers. At Amubri, in southern Talamanca, Costa Rica, a *D. auratus* jumped into a pond and apparently was unable to return to the surface again. It looked as if it was about to "drown," when rescued by the junior author. However, during drier periods in the tropical wet forest, *D. auratus* has been observed to congregate in wet areas, i.e. near small streams (Myers and Daly 1976. Bull. Am. Mus. Nat. Hist. 157(3):175-262.

We thank Dr. W. Bussing and Dr. D. Robinson, at the University of Costa Rica, for identifying the fish species and comments on an earlier draft of the manuscript, respectively.

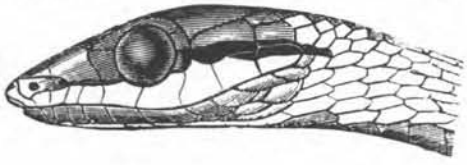
CAUDATA



ENSATINA ESCHSCHOLTZII OREGONENSIS (Oregon ensatina). **REPRODUCTION.** A total of three natural nest sites for this subspecies has been reported from western Washington state [Norman and Norman 1980. Bull. Chicago Herp. Soc. 15:99-100; Jones and Aubry 1985. Herp. Review 16(1):26]. These reports describe nest site micro-habitat preference for western Washington populations of this subspecies in qualitative terms.

On 25 May 1986, the discovery of two further brooding females in logs near Woods Creek Rd., ca. 8 km N of Monroe, Snohomish Co., Washington, provided an opportunity to quantitatively compare the sites in terms of dimensions and situation. Overall qualitative situation was similar to that previously reported.

Data for nest site A is followed by respective data for nest site B after appropriate heading. Time of discovery: 1605 h; 1705 h. Depth in log: 6 cm; 4 cm. Height of nest from forest floor: 35 cm; 35 cm. Shortest distance from nest chamber to end of log: 20 cm; 135 cm. Length of decomposing log: ca. 5.9 meters; incalculable. Diameter of log: ca. 61 cm; ca. 61 cm. Greatest length of egg chamber: 10 cm; 5 cm. Greatest height in nest chamber: 3 cm; 2.5 cm. Greatest width of nest chamber: 3 cm; 4 cm. Number of eggs: 9; 8. Diameter of eggs: $\bar{X}$ 6 mm; $\bar{X}$ 5 mm. Greatest length of egg cluster: 19 mm; 16.5 mm. Width of egg cluster perpendicular to greatest length: 15 mm; 11 mm. Female SVL: 56 mm; 51 mm. Light conditions: shade; shade. Distance between nest sites: 29 m.

Contrary to earlier reports, specific examination of the egg clusters revealed no adherence to the substratum. One adult male and two juvenile *Ensatina*, all exhibiting characteristic coloration, were recorded at the same locality on 25 and 26 May 1986. *Plethodon vehiculum* was present in similar situations but never in the same log as *Ensatina* (N=8 logs). Voucher specimens are deposited in the James R. Slater Museum of Natural History, University of Puget Sound, Tacoma, WA.

Submitted by **BRADFORD R. NORMAN,** 21015 86th Ave. SE, Snohomish, Washington 98290, USA ●

SAURIA

LEIOCEPHALUS SCHREIBERSI (Curly-tailed Lizard). **TAIL AUTOTOMY.** Much literature has been devoted to tail autotomy in lizards as an adaptation for avoiding predation (Arnold 1984. J. Nat. Hist. 18:127-169; Bellairs and Bryant 1985. *In:* C. Gans and F. Billett (eds.), Biology of the Reptiles, Vol. 15, Development B. Pp. 301-410. John Wiley and Sons, New York.; Congdon et al. 1974. Science 1984:1379-1380; Daniels 1983. Herpetologica 39:162-165; Vitt 1983. Herpetologica 39:151-162). Because observations of predation in the field are rare, there has been considerable use of the frequency of regenerated tails in field populations as evidence for predation pressure. However, tail breaks really represent injuries of unknown origins and could result from conspecific fights as well as failed attempts of predators (Schoener 1979. Ecology 60:1110-1115; Schoener and Schoener 1980. Copeia 1980:839-850; Vitt et al. 1974. Copeia 1974:990-993; Tinkle and Ballinger 1972. Ecology 53:570-584). Still another source of tail autotomy, and one not commonly considered, is courtship. Where male-male fighting can explain tail breaks in males, courtship accidents are an alternative explanation to attempted predation as a cause for regenerated tails in females. The following anecdote illustrates how observed female tail breaks could be the result of courtship.

On 17 June 1985 at 1530 h on a beach 6 km south of Montrois, Haiti, we were conducting a population census of *Leiocephalus schreibersi* and saw a large male *L. schreibersi* make a quick dash of ca. 0.5 m and grab a retreating adult female by her tail. She struggled and her tail was severed. Approximately 2.5 cm of the tail segment lay wriggling vigorously on the ground as the male lunged and secured a neck hold on the female before she moved again. This was followed by copulation which lasted only several seconds. The male then released the female and performed several bouts of head bobbing as the female moved away. The tail, which was still undulating ca. 30 cm from the male, attracted his attention. The male moved over to the tail and ate it.

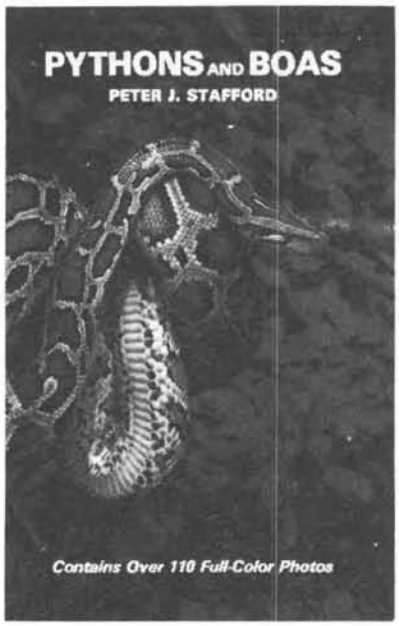
SERPENTES

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). **REPRODUCTION.** This subspecies has been known to have litter sizes of 2 to 8 offspring. On 18 July 1972 at Ojo de Agua at Pablillo, Nuevo Leon, Mexico a gravid female (SVL 520 mm) was collected by Ernest A. Liner, Richard M. Johnson and Allan H. Chaney. On 1 August 1972 she gave birth to 9 young. They measured 146-178 mm; $\bar{X}$ = 165.7 mm. The mother (EAL 3096) and the young (EAL 3293) were deposited in the private collection of Ernest A. Liner.

Submitted by **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70364-2598, USA and **ALLAN H. CHANEY,** Department of Biology, Texas A & I University, Kingsville, Texas 78363, USA ●



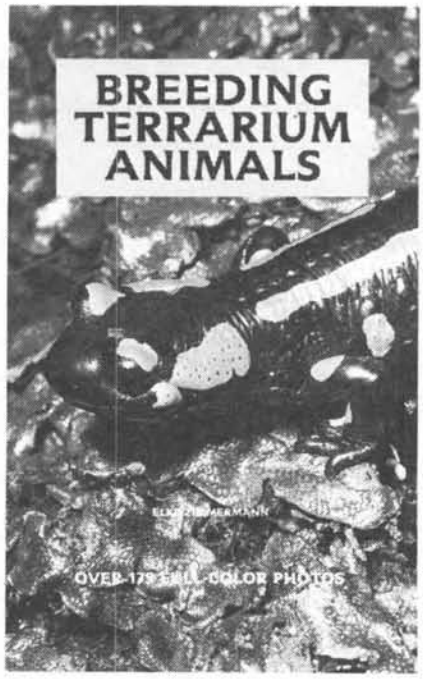
CROTALUS PRICEI MIQUIHUANUS (Miquihuanan Twin Spotted Rattlesnake). **REPRODUCTION.** Armstrong and Murphy (1979. Special Publ. 5, Univ. Kans. Mus. Nat. Hist., pp. 42-43) reported on the only two known litters (4 and 5) of this subspecies. On 20 July 1985 a gravid female (SVL 303 mm) was collected 1.8 km N Las Mimbres (by road) at jct. San Juan de Mimbres road, 2499 m, Nuevo Leon, Mexico by Ernest A. Liner and Allan H. Chaney. She died on 24 July 1985 before giving birth, but 6 full term young were removed by dissection. The four males ranged from 114 to 116 mm SVL, $\bar{X}$ = 115 mm. The two females ranged from 118 to 120 mm SVL, $\bar{X}$ = 119 mm. The mother is now cataloged as EAL 5021 and the young as EAL 5033 in the private collection of Ernest A. Liner.

Submitted by **ALLAN H. CHANEY,** Department of Biology, Texas A & I University, Kingsville, Texas 78363, USA and **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70364-2598, USA ●

TESTUDINES

STERNOTHERUS MINOR (Loggerhead Musk Turtle). **SIZE.** On 18 March 1986 a large male *Sternotherus minor* was collected by Carlos D. Camp and David P. Keener on the east bank of the Ocmulgee River at the Georgia 16 bridge, Jasper Co., Georgia. Carapace length (CL) of the specimen was 144 mm while carapace width measured 99 mm. This specimen exceeds the maximum CL of both males (124 mm) and females (133 mm) examined by Iverson (1977. Copeia 1977(3):502-517) as well as the record for the species (135 mm) given by Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Cen-

USEFUL NEW HERPETOLOGICAL TITLES FROM T.F.H.



PYTHONS AND BOAS • **Peter J. Stafford**

Pythons and boas have long been among the most fascinating of snakes, and with continued encroachment upon their habitat they are now also among the most threatened. *Pythons and Boas* provides an up-to-date look at the Boidae, with emphasis being placed on the boids as threatened animals whose futures lie with increased captive breeding by concerned hobbyists. Every genus is covered, from the largest pythons to the smallest wood snakes, with summaries of what is known of their natural history and care in captivity. A special chapter spotlights methods of breeding boas and pythons in captivity. This volume includes the only available modern checklist of the species and subspecies of living boids, as well as a simple key to the genera. Heavily illustrated, with 111 color photos and numerous black and white illustrations and maps.

BREEDING TERRARIUM ANIMALS •
Dr. Elke Zimmermann

Breeding Terrarium Animals provides the much-needed guidance to this often complicated phase of the terrarium hobby. The author presents her experiences and those of her colleagues in condensed but very readable form filled with information of use to hobbyists and professional herpetologists alike. Profusely illustrated in color, the book covers almost 100 species in detail, with basic information on dozens more. For the main species there are discussions of care, identification, and distribution, followed by detailed observations on the breeding behavior, incubation, and care of the young. The other species are grouped with the major species by their similarity in breeding behavior and listed with such essentials as number of eggs, incubation period, and temperature preference. In total, almost 350 species are covered, from axolotls to *Xenopus* among the amphibians and agamas to *Xantusia* among the reptiles. The discussions of the complicated life histories of the fascinating poison arrow frogs (*Dendrobates* and *Phyllobates*) are especially detailed. Good discussions of general terrarium maintenance, rearing food animals, and methods of egg incubation round out the book.

TRIONYX SPINIFERUS (Spiny Softshell Turtle). **SIZE.** A possible record size for an undetermined subspecies of *Trionyx spiniferus* was exhibited by a female specimen captured 4 October 1985 in Ouachita Parish, Louisiana. The specimen, exhibiting a deep camouflage pattern on the carapace typical of old females, had a mass of 11.7 kg and possessed the following morphometry: carapace length = 54.0 cm, carapace width at widest point = 40.6 cm, plastron length = 36.2 cm and tail length = 22.2 cm. The female was taken in 5 ft of water by a 3 ft diameter hoop net in a paper plant impoundment, Wham Brake, located ca. 10 mi NE of Monroe, Louisiana off the south shoreline about 1 mi W of the spillway. Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) listed the upper limit in carapace length for *T. spiniferus* as 18 in (46 cm); and Lagler (1943. Amer. Mid. Nat. 29:257-312.) mentioned "more than 16 in (40.6 cm)" as maximum size.

Subspecies designation was not assigned to the large female *Trionyx* because of physical changes associated with age, sex, and intergradation. In Mississippi, Arkansas, and Louisiana there are intergraded populations of *T. spiniferus* that have characteristics of the three subspecies, *harwegi, spiniferus,* and *aspera* (Carr 1952. Handbook of Turtles, Comstock, Ithaca.).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

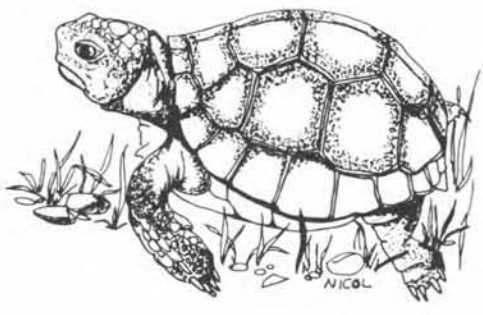
BUFO DEBILIS DEBILIS (Eastern Green Toad). USA: TEXAS: Johnson Co: 14.5 km NE Glen Rose on County Rd. 1234, Ken Fry Ranch. 8 June 1986. C. T. McAllister. Arkansas State University Museum of Zoology (ASUMZ 5997). Somervell Co: 1.6 km SW Nemo off FM 199 on County Rd. 402. 22 and 29 June 1986. C. T. McAllister. (ASUMZ 6013-6014, 5970-5976). Both verified by S. E. Trauth. New county records, fill north-south distributional gaps in a four-county area (Raun and Gehlbach 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. No. 2) and near eastern edge of species' range (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston xviii + 429 pp.).

Submitted by **CHRIS T. MCALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical Center, Dallas, Texas 75216 and **KENNETH L. FRY,** Star Route, Box 39A, Nemo, Texas 76070, USA. ●

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: NEW MEXICO: Luna Co: 8.8 km E and 1.6 km S Hermanas. 27 June 1986. W. G. Degenhardt. Verified by W. G. Degenhardt. Museum of Southwestern Biology, The University of New Mexico (MSB 47045). New state record. Venter unmarked; dorsum grey with some spotting; femur and tibia spotted, but spots do not form a distinct bar when the limb is folded. Subspecies is problematic.

Submitted by **WILLIAM G. DEGENHARDT,** Museum of Southwestern Biology, Department of Biology, The University of New Mexico, Albuquerque, New Mexico 87131, USA. ●

HYLACTOPHRYNE AUGUSTI LATRANS (Eastern Barking Frog). USA: NEW MEXICO: Otero Co: New Mexico Hwy 506, 9.7 km N Texas state line, T25S-R18E-S34. 19 August 1985. A. H. Price. Verified by A. H. Price. New Mexico State University (NMSU 6545). New county record, extends range ca. 85 km west of Pecos River drainage across Guadalupe Mountains (Schmitt et al. 1985. Handbook of species endangered in New Mexico, AMPH/LE/HY/AU: 1-2. New Mexico Dept. of Game and Fish, Santa Fe). The species may occur relictually throughout the Otero Mesa, New Mexico and the Diablo Plateau, Texas. Collection supported by Contract No. 516.6-74-10, Endangered Species Program, New Mexico Dept. of Game and Fish.



Submitted by **ANDREW H. PRICE,** Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. Present address: Texas Natural Heritage Program, General Land Office, Austin, Texas 78701, USA. ●

PSEUDACRIS STRECKERI STRECKERI (Strecker's Chorus Frog). USA: ARKANSAS: Sebastian Co: 5 km E Slaytonville. 25 March 1986. W. Fesperman. Verified by S. Fox. Oklahoma State University Museum of Zoology (OSUS A6323). New county record, extends range into mountainous section of Arkansas River Valley Region (Dowling 1957. Occas. Papers Univ. Arkansas Mus. 3, 51 pp.).

Submitted by **WILLIAM FESPERMAN,** Oklahoma State University, Department of Zoology, Stillwater, Oklahoma 74078, USA. ●

SCAPHIOPUS HOLBROOKII HOLBROOKII (Eastern Spadefoot). USA: OHIO: Washington Co: City of Belpre. 22-25 June 1986. J. Hill and S. Moody. Verified by D. Rice and S. Moody. Ohio University Vertebrate Collection (OUVC 8490-8493). New county record, third record for Ohio. (Green 1948. Copeia 1948(1):65). Extends range ca. 48 km E of Northernmost locality, Athens (Wasserman 1968. Cat. Amer. Amphib. Rept. 70.1-70.4).

Submitted by **SCOTT M. MOODY,** Department of Zoological and Biomedical Sciences, and Ohio University Vertebrate Collection, Ohio University, Athens, Ohio 45701, USA. ●

CAUDATA

AMBYSTOMA GRACILE (Northwestern Salamander). USA: ALASKA: Chichagof Island: Pelican (Lat. 57°57'N, Long. 136°13'W). Five adults collected (14/7/81, 6/1982, 6/1985, 9/1985) by residents and students of M. A. Davidson, PHS teacher. Verified by R. P. Hodge and M. A. Davidson. Tongass Historical Society Museum (THSM P32, 101, 102, P33). Extends range 437 km NW of May (Mary) Island (Hodge 1976. Amphibians and Reptiles of Alaska, the Yukon & Northwest Territories, Alaska Northwest Pub. Co., Anchorage xi + 89 pp.).

Submitted by **ROBERT PARKER HODGE,** c/o Tongass Historical Society Museum, 629 Dock Street, Ketchikan, Alaska 99901, USA. ●

HEMIDACTYLIUM SCUTATUM (Four-Toed Salamander). USA: ARKANSAS: Cleburne Co: 3.5 km W Concord (T12N R8W S19). 17 April 1984. T. Tharp. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 6020). New county record (Dellinger and Black 1938 Occ. Pap. Univ. Arkansas Mus. 1:1-47; Dowling 1957. Occ. Pap. Univ. Arkansas Mus. 3:1-51) first record for Ozark Mountain Region in Arkansas (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston xviii + 429 pp.).

BOOK REVIEWS

Virginia's Amphibians and Reptiles, A Distributional Survey, by Franklin J. Tobey. 1985. Privately published by the Virginia Herpetological Survey. 114 pp.

This publication is the result of the primary activity of the Virginia Herpetological Society during the period 1958-1980 and, more than anything else, is a tribute to the untiring efforts of one amateur herpetologist, F. J. Tobey. Most of the publication presents the set of distribution maps for Virginia's amphibians and reptiles. Common and scientific names follow Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). Each specific locality is represented by a black dot on county-outlined maps. There are two maps per page and each has several lines of text on distributional notes, historical records and literature notations. In addition, there are maps illustrating physiographic regions and major drainage patterns, and line drawings of the three venomous snake species. An index is included and is cross-referenced with Conant's field guide. The publication is 8½ x 11 inches in size. The only printing problems were slightly blurred pages (50, 59) in one of our copies, and some of the scientific names (in italics on the maps) printed lightly, although all can be read. The scientific name of *Thamnophis sauritus* is incorrect, but we found few typographical errors. The map for *Eurycea bislineata wilderae* is out of place.

We commend Tobey on the much needed compilation of a massive data base. He has taken great pains to seek out literature records from obscure sources. The historical information alone credits the work. In addition, Tobey has included an interesting, although somewhat rambling, discussion of the origins of attitudes toward amphibians and reptiles, sources and fate of introduced species, sources of the survey data, conservation, and the justification for preserved material. Much of this is useful advice, especially for the general reader.

One of our primary concerns is that the locality records are largely based on unverified lists of specimens from museum and university collections and that an undetermined number are based on unverified observations reported to Tobey via correspondence. Virtually all localities are represented by solid black dots, including literature and correspondence records. It would have been desirable to distinguish between verified and unverified sites. The problems generated by these procedures attest the need to verify (reidentify) specimens, at the very least at range margins, before localities are posted on distribution maps. Acceptance of unverified and unverifiable information is a dangerous practice.

The proper treatment of subspecies is a controversial point. Tobey has clarified his view by including as an appendix a note written by the late James A. Peters to the Virginia Herpetological Society in 1965. This note provides an excellent summary of the subspecies concept and points out the pitfalls encountered with attempts to apply a typological view. Yet, the maps of each subspecies are presented separately in the Virginia survey. This only reinforces misunderstandings of the subspecific taxon and, in our experience, proves confusing to many potential users of the survey. The succinct mention of a few localities with intergrades does little to clarify the misunderstanding.

Once the most important distributional problems are clarified (Mitchell and Pague, in press, Herp. Review), the maps in this publication can be considered reasonably accurate and useful. Despite the errors, F. J. Tobey and other VaHS workers are to be commended for the efforts they have put into this long-term project. The result certainly demonstrates the contribution an amateur herpetological society can make. These maps provide the basis for further elucidation of the ranges of these species in Virginia. In particular, amateur herpetologists now have the basis for determining where the distributional gaps are and can make contributions to our understanding of biogeographical patterns. Because these maps are the most comprehensive to date, they will also be useful to those studying distributional patterns on a national scale.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1986

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Henri C. Seibert
SSAR Treasurer
Department of Zoological and Biomedical Sciences
Ohio University
Athens, Ohio 45701, U.S.A.

SSAR BUSINESS

1987 ANNUAL MEETING

The 1987 SSAR/HL Annual Meeting will be held 9-15 August in Veracruz, Veracruz, Mexico. The Institute of Biology of the National Autonomous University of Mexico will be the host institution. The meeting site will be Hotel Mocambo, a large hotel with an informal atmosphere located 10 min from the airport on the south end of Veracruz, 200 m from the beach. There are eight other large hotels in the immediate vicinity as well as two camping/trailer parks within 2 km.

Besides the low prices, congenial atmosphere, excellent food, tropical refreshments, and tropical weather, there are numerous interesting ecosystems to *observe* herps in their natural habitats. Field trips are being planned to Mt. Orizaba, the swamps of Lerdo de Tejada, Estación de Biología Tropical "Los Tuxtlas," and Volcan Santa Martha. Family excursions will include the Mayan ruins of Tajín, San Juan de la Ulúa (prison of the Spanish Inquisitions), local museums, and tourist shopping. Local entertainers including, but not limited to, Marimba, Mariachis, and Salsa groups will perform nightly. Time permitting, there will also be paper sessions.

Discount air fares have been arranged. Contact Ray Ashton at Holbrook Travel, 3520 NW 13th Street, Gainesville, Florida 32609, phone 1-800-451-7111. Please specify to receptionist that you are making reservations for the SSAR/HL conference.

Richard C. Vogt and Gustavo Casas Andreu are co-chairpersons for the meeting.

PRE-PAY YOUR SSAR DUES; SAVE YOUR TAX DEDUCTION

Revisions in US tax law may eliminate the deduction allowance for dues to unions and professional societies. Persons who itemize their return are encouraged to pre-pay annual dues in 1986 for up to the next three years, allowing the entire deduction to be taken on 1986 returns. ●

SSAR LIFE MEMBERSHIPS ONE TIME OFFER

Tax law revisions may eliminate deductions for dues to unions and professional societies. The SSAR Board has reinstituted the Life Member category, and persons who join as life members may take the full deduction in 1986.

Life membership cost is $550.00. While this amount may seem high, bear in mind that the cost of life memberships has always SEEMED high, but over the years life members have saved money and time. Life members are on record as life-time supporters of the Society.

Under 1986 tax law, payment of $550.00 will generate a refund of $148.50 for taxpayers in the 27% bracket. This may be the only way to realize this sort of return for years to come.

Rid yourself of the worries of dues increases, annual renewals, and possible loss of future deductions by selecting the Life Member category now. Your action now helps SSAR and gives you deductible expenses this year. ●

SSAR Grants-In-Herpetology, 1986

The Society for the Study of Amphibians and Reptiles is pleased to announce the awards made by the Grants-In-Herpetology Program for 1986.

GRADUATE STUDENT RESEARCH

Barry Sinervo, Department of Zoology, University of Washington, Seattle, Washington 98195, $430. "Thermal physiology of growth in field populations of Sceloporus lizards: genetic and environmental aspects."

John L. Carr, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, $354. "Phylogenetic analysis of the Neotropical emydid genus *Rhinoclemmys.*"

HERPETOLOGY-ORIENTED CONSERVATION

Franz J. Kutka, Department of Animal Ecology, Iowa State University, Ames, Iowa 50011, $430. "The threat of habitat acidification to the Ambystomatid salamanders of Michigan."

FIELD WORK

Byron Wilson, Department of Zoology, University of Washington, Seattle, Washington 98195, $430. "A study of latitudinal patterns of mortality in ***Uta stansburiana.***"

No proposals were received from Regional Herpetological Societies and no award was made in the category of Herpetological Research in Zoos.

THOMAS H. FRITTS, CHAIR
SSAR Grants-In-Herpetology Committee ●

ANNUAL MEETING ABSTRACTS AVAILABLE

Several copies of the abstracts of papers presented at the 1986 SSAR/HL Annual Meeting are available for sale. Price to a US address is $5.00, postpaid. For non-US orders, add $1.75 (surface) or $4.50 (air). US funds only, please. Make checks payable to SSAR.

Address orders to:
Dr. Douglas Taylor
Department of Zoology
Miami University
Oxford, Ohio 45056, USA ●

SPONSORSHIP OF NON-U.S. MEMBERS

SSAR is expanding its sponsorship of non-U.S. members by requesting contributions to a fund established to defray the membership dueś of herpetologists in countries that face difficulties with exchange of foreign currency. We encourage your participation in this program. Please contact our Treasurer, Dr. Henri C. Seibert, if you can assist in the identification of colleagues who can benefit from this program. All contributions are tax deductible. ●

NEWSNOTES

ONTARIO HERPETOFAUNAL SUMMARY

The Ontario Herpetofaunal Summary is a volunteer project designed to gather and publish distributional and ecological data on Ontario amphibians and reptiles. Initiated in

1984, the Summary is now in its third year, with funding support from the World Wildlife Fund and Essex Region Conservation Authority. Contributors to the Summary are asked to fill in cards on sightings of amphibians and reptiles; these cards are available from the compilers. Plans are underway for a 5-year herpetofaunal atlas beginning in 1987. Such an atlas would map the distribution of the province's amphibians and reptiles by 10 km^2 squares for southern Ontario and 100 km^2 squares for northern Ontario.

Copies of sightings cards and the 1984 Ontario Herpetofaunal Summary are now available. The Summary is 214 pp. long, with 51 species accounts. Each account contains a distribution map, comments on the current and historic distributions, a list of sightings in each county, and a bibliography. The Summary may be ordered for $15 Canadian ($13 US) from:

Michael J. Oldham
Essex Region Conservation Authority
360 Fairview Avenue West
Essex, Ontario N8M 1Y6, Canada ●

CALL FOR PAPERS

All professional and amateur herpetologists are invited to submit for consideration the titles of papers they wish to present at the 11th Annual International Herpetological Symposium on Captive Propagation and Husbandry. The meeting will be held in Chicago, Illinois during June, 1987. Paper lengths should be 20-30 minutes. A brief Abstract of the proposed talk should be submitted to Sean McKeown within 30 days after receiving this issue of *Herpetological Review*.

NON-RELEASABLE ANIMAL PLACEMENT PROGRAM

The Animal Rehabilitation Center, Inc. of Midlothian, Texas will be coordinating the mammal, reptile and amphibian sections of the San Francisco Zoological Society's Non-Releasable Animal Placement Program (NAPP). This program is a computer-based information system for non-releasable species of mammals, birds, reptiles and amphibians. Its purpose is to maintain a clearinghouse for wildlife professionals who deal with non-releasable, permanently injured or imprinted animals. It is designed for the placement of surplus animals into various programs throughout North America.

"Availability" or "Request" forms, or further information, may be obtained from:

Animal Rehabilitation Center, Inc.
449 Edgefield Lane
Midlothian, Texas 76065, USA ●

INDIAN TURTLE FIELD GUIDE

The World Wildlife Fund — India has available for sale "Indian Turtles — A Field Guide" by Indrancil Das. The volume is 119 pages, paperback, and has numerous b & w illustrations. It was printed in 1985. The cost is Rs. 35.00 plus postage from India. Write to:

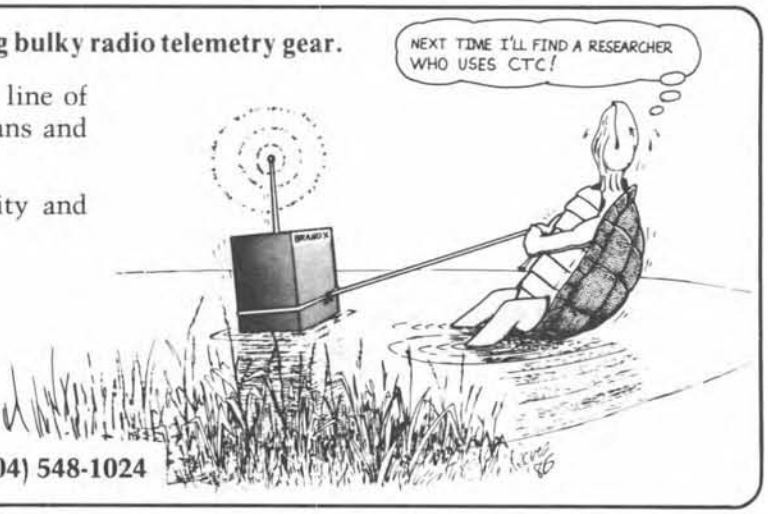
WILDLIFE REHABILITATION GRANTS AND AWARDS

The National Wildlife Rehabilitators Association announces a small-grants program and the establishment of two awards. The grant makes funding available to support a single $1000 project or several smaller projects that total $1000 in the field of wildlife rehabilitation. Applicants must demonstrate financial need and submit a typewritten proposal that includes name(s) and resume of personnel involved, objectives of the project, a brief description of how the project will be carried out, a brief statement of the literature reviewed and an itemized budget. An annual report on progress is required.



The awards include the Lifetime Achievement Award given to an individual whose primary identification is with rehabilitation of wildlife and who has contributed to this field in a major way for many years. The Signifi-

No species of study should be burdened with carrying bulky radio telemetry gear.

Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

Custom design, high quality components, reliability and reasonable prices...that's *CTC*.

Please inquire for more detailed information.

Custom Telemetry & Consulting, Inc.

185 Longview Drive □ Athens, Georgia 30605 □ (404) 548-1024

cant Achievement Award is for a person who has contributed something of merit to the field in the last two years. The contribution may be a research finding, publication, organization of a program, etc., with a major theme in wildlife rehabilitation. Both awards consist of a plaque, $100, and free registration at the NWRA conference where the award will be presented. The deadline for submittal of proposals for the grant or nominations for the awards is December 1 of each year. They should be sent to:

Daniel R. Ludwig, Ph.D.
Awards and Grants Committee
Willowbrook Wildlife Haven
Willowbrook Forest Preserve

JOINT ICHTHYOLOGY/ HERPETOLOGY TRIP TO THE AMAZON

Dr. Bob Stiles, ichthyologist at Samford University, and Dr. Ken Marion, herpetologist at the University of Alabama at Birmingham, will lead a joint seven-day ichthyology/herpetology field trip to the Peruvian Amazon. The departure date from Miami is January 11, 1987. A licensed 76-foot two-deck river boat, the M/V Margarita, will serve as the base of operations. The ship has bathroom facilities, a dining room and comfortable sleeping quarters.

Stops will be made at unique habitats on the River for the purposes of seining, observation, and herpetological journeys into the rain forest. The Margarita is equipped to hold fish. Appropriate arrangements for specimen collection can be made. The cost is $1695 all inclusive from Miami. For more information, contact Dr. Bob Stiles at (205) 870-2928 or Dr. Ken Marion at (205) 934-3582 as soon as possible. Other information can be provided by writing Ken Marion, Biology Department, UAB, Birmingham, Alabama 35294. ●

ASZ AND FIVE OTHER SOCIETIES TO MEET IN NASHVILLE, TENNESSEE

The 1986 Annual Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, International Association of Astacology, and the Society of Systematic Zoology will be held at the Opryland Hotel in Nashville, Tennessee during the traditional post-Christmas period, 27-30 December 1986.

Symposia presently scheduled are: (1) Energetics and Animal Behavior, (2) The Comparative Endocrinology of the Thyroid, (3) Phylogenetic Development of Self-Non-Self Recognition, (4) Cutaneous Exchange of Gases and Ions, (5) Nervous System Regeneration in the Invertebrates, (6) Habitat Selection and Evolution, (7) Philosophical and Theoretical Issues in Systematics, (8) Axial Movement Systems: Biomechanics and Neural Control, (9) Vertebrate Morphology: A Tribute to Milton Hildebrand, (10) History of American Marine Biology and Marine Biology Institutions, and (11) Science as a Way of Knowing—Developmental Biology.

The Division of Developmental and Cell Biology is presenting three special sessions: (1) Intercalation Mechanisms in Pattern Formation, (2) New Approaches to the Cell Biology of Limb Regeneration, and (3) The Role of Matrix in Development.

In addition, a workshop on *Applications of Histochemistry to Microscopy. II. Immunocytochemistry* will be offered by the American Microscopical Society.

The Genetics Association of America will sponsor the Wilhelmine E. Key Lecture by Dr. Bruce Wallace, titled, "Closing the Ring: Fifty Years of Genetic Load."

Meeting plans include several socials, special programs, commercial exhibits and a Job Placement Service. Housing and Registration deadlines are November 20. Forms are now available.

This meeting is hosted by Vanderbilt University, with Burton J. Bogitsh and Mafoi C. Bogitsh co-chairing the Local Arrangements Committee. For more information contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, Box 2739 California Lutheran University, Thousand Oaks, California 91360, USA. (805) 492-3585. ●

IN MEMORIAM

COLEMAN J. GOIN, 1911 - 1986

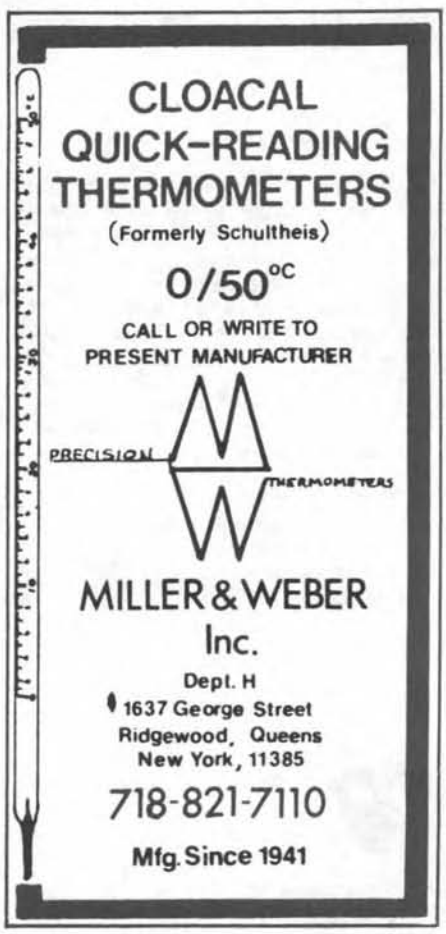
Coleman Jett Goin was born in Gainesville, Florida on 25 February 1911. He received his academic training at the University of Florida (B.S., 1939; M.S., 1941; Ph.D., 1946), and joined the faculty of the Department of Biology there in 1942. In 1971 he retired as Emeritus Professor of Biological Science and moved to Flagstaff, Arizona, where he was associated with the Museum of Northern Arizona and Northern Arizona University. He remained in Flagstaff until his death on May 12, 1986.

Coleman Goin specialized in amphibians, and studied all aspects of amphibian biology, including behavior, systematics, and even fossils. He published prolifically on the amphibians of his native Florida, often in collaboration with his wife, Olive B. Goin, who is a trained biologist in her own right. The team of Goin and Goin is probably best known for their textbook "Introduction to Herpetology," now in its third edition (with co-author George R. Zug). Goin also worked on the amphibians of Jamaica and northern South America. His work on Neotropical frogs culminated in the massive "Frogs of Colombia" (1970), co-authored with Doris M. Cochran.

In addition to his herpetological research, and a full teaching schedule, Goin wrote a number of books, including the immensely popular textbook "Man and the Natural World" by Goin and Goin, the "New Field Book of Reptiles and Amphibians" (with Doris M. Cochran), and "Guide to the Reptiles, Amphibians, and Fresh-water Fishes of Florida" (with Archie Carr).

Coleman Goin, known to friends as "Coly," was a man of uncompromising personality. To those who, in his opinion, warranted criticism he was the most outspoken of critics. To those he befriended he was the most steadfast and loyal of friends. Herpetology is fortunate that his influence will continue to be felt through "Introduction to Herpetology."

C. J. McCOY
Carnegie Museum of Natural History
Pittsburgh, Pennsylvania 15213, USA ●



SOCIETIES

GAINESVILLE HERPETOLOGICAL SOCIETY

The Gainesville Herpetological Society was established in September 1985 and presents a forum of communication for anyone interested in herpetology. The Society promotes the scientific study and conservation of amphibians and reptiles worldwide. Regional education is emphasized but our activities address many herpetological subjects.

Dissemination of information is accomplished by monthly meetings and the Gainesville Herpetological Society Newsletter. The monthly meetings highlight guest speakers which have included Dr. W. Auffenberg, P. Moler, Dr. M. Crump, Dr. H. Lillywhite, Dr. E. Jacobson and Dr. L. H. S. Van Mierop. The Newsletter, published monthly, contains articles and comments on many herpetological subjects.

Activities during this first year have included public educational programs, excursions to state preserves, Silver Springs, Santa

Fe Community College Teaching Zoo and Jumbolair Ranch. The Society also acted as co-sponsor for the 9th Annual All Florida Herpetological Conference with the Florida State Museum.

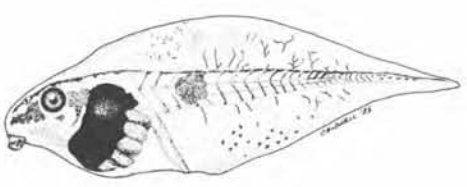
The Society encourages liaison between members, the public and other herpetological societies to promote education for the welfare of amphibians and reptiles. With a current membership of over 100, combined with support from the distinguished herpetological community inherent in Gainesville, we fully expect to continue as a positive and productive Society.

Annual membership is $8 and correspondence may be directed to:

Gainesville Herpetological Society
P.O. Box 7104
Gainesville, Florida 32605, USA ●

ONTARIO HERPETOLOGICAL SOCIETY

The Ontario Herpetological Society is a non-profit organization dedicated to the education of its members and the general public in the conservation, captive husbandry and scientific knowledge of reptiles and amphibians. Membership is open to anyone with an interest in reptiles and amphibians whether or not they maintain a collection of these animals.



THE ONTARIO HERPETOLOGICAL SOCIETY NEWS is published quarterly. The newsletter contains original and reprinted articles in the field of herpetology as well as classified advertisements. THE JOURNAL OF THE ONTARIO HERPETOLOGICAL SOCIETY is published annually and contains longer and more specialized articles. Members are encouraged to submit articles for either publication.

Meetings are held bi-monthly from September through May at the Innis College Cafe, 2 Sussex Ave., University of Toronto. Interested persons and all family members are urged to attend as the bar is closed during meeting times, 7:30 pm till 9:30 pm. Each meeting will feature a presentation by a member or guest speaker.

In addition to meetings, future activities include field trips and live animal displays in public areas (shopping malls, libraries, seniors homes, Girl Guide and Boy Scout meetings).

For further information contact:

Ontario Herpetological Society
P.O. Box 130 Stn. G
Toronto, Ontario
M4M 3E8 CANADA ●

INDIAN HERPETOLOGICAL SOCIETY

The Indian Herpetological Society has recently been formed to promote the study of herpetology in India. The society forms a central body of herpetologists which gathers information from all sources, exchanges programmes on various levels, and maintains contact with similar bodies worldwide. The society also plans to develop a highly advanced herpetological documentation centre. All interested individuals are requested to submit reprints and pictures of herptiles from their regions.

Annual Subscription: Rs. 200
U.S. $20

ANIL KHAIRE, Treasurer
Indian Herpetological Society
'USANT'
Poona Satara Road
Poona 411 009, INDIA ●

FEATURES

IN DEFENSE OF PRIVATE COLLECTIONS

Strongly negative viewpoints regarding private collections of preserved herpetological material have periodically been expressed in *Herpetological Review*. The Committee on Resources in Herpetology recommended unequivocally that "all specimens . . . should be deposited in institutional collections" (*HR* 6(2):34), and the Joint Herpetological Resource Committee, in the second list of museum acronyms (*HR* 11(4):93-102) omitted all private collections on the grounds that the important ones are ultimately deposited in recognized institutional collections, and because the Committee did not want to encourage the proliferation of non-institutional collections by affording recognition to those already in existence. Also, the preambular remarks to the Geographic Distribution section of *Herpetological Review* under the editorships of Joseph Collins and Ellen Censky include wording that *requires* identification of the place of deposition and catalog number of specimens on which range extensions are based, and *discourages* private collection depository records, although it is not entirely clear if it is the placement of specimens in private collections or the reporting of such placement — or both — that is being discouraged. However, exceptions have been made, e.g. the Ohio *Chelydra serpentina* or the California *Caretta caretta* (*HR* 12(1):15).

I largely share this philosophy, and would certainly not offer encouragement to the young, or to the less than dedicated, to start private collections of preserved reptiles and amphibians. However, private collections do exist. Some excellent ones were accumulated by some of the great names in herpetology (e.g. Arthur Loveridge and Laurence Klauber). Moreover, because collections of non-protected species cannot be outlawed in most countries, and because they sometimes include important specimens, nothing is gained by pretending that they do not exist. To argue that they need not be publicized because they will ultimately be incorporated into institutional collections is to condemn them to inaccessibility to other workers for decades, or even a lifetime. Moreover, I do not believe that private collections should be discouraged under all circumstances. I maintain a private collection within my own field of interest (turtles and tortoises) that currently includes 236 taxa and over 2000 specimens, and since the viewpoint in favor of such collections is not often heard, I would like to express some arguments giving qualified justification to the accumulation of private collections such as mine.

Common sense suggests that at least certain private collections are acceptable, or at least inoffensive. A young herpetologist may preserve and keep the remains of captive specimens that die, or a mature worker will often keep series of specimens he has collected and on which he is actually working, at least for the duration of his study. In the case of long-term or lifelong studies, such specimens will constitute an *ipso facto* private collection. Moreover, public collections have a finite capacity for specimens of common species, especially bulky or incomplete ones or those lacking collecting data, and they show an understandable lack of enthusiasm in accepting such material. An alternative to the discarding of such specimens is that they be kept by an individual who has an interest in them. So far so good.

Divergence of opinion starts when a private collection achieves a point of quantity or quality at which it has real scientific value and would be received gladly by an institution. It is perhaps harsh to expect owners of private collections to dispose of them just at the time the collection becomes significant, but objections to a collection remaining private are generally as follows:

a) Private collections may collectively constitute a demand for specimens of rare or local species that may threaten the population integrity or even survival of such forms.

b) Private collections may not be easily accessible, or even known, to other workers.

c) Private collections may be dispersed or discarded after the owner's death.

d) Holders of private collections may lack the time or resources to curate them properly.

These are legitimate concerns, but all are answerable.

a) It is not appropriate for holders of private collections to collect or sacrifice live specimens of rare species for their collections. My own philosophy, even more conservative, dictates that I only incorporate specimens that have not been sacrificed for this purpose, but that were found dead in the wild or that died in captivity. Specimens found dead and prepared into skeletons may be of greater scientific value than complete and mounted museum specimens, which have many critical features inaccessible.

Neither holotypes nor paratypes of any organism should be kept in private collections. However, specimens listed in the "hypodigm" of a new species may be housed in private collections if they are not part of the type series. Authors such as Cagle (1954) included in the hypodigm of new species individuals that were dissected and discarded, and even those that were seen but not captured.

b) Once a private collection achieves signif-

icant value, its existence should be publicized through appropriate media and, if possible, a catalog of specimens published or made available to other workers. Specimens should be available on loan to qualified individuals.

The question of publication of catalogs of museum holdings is a critical one for both private and public collections. Major museums (especially the BMNH) have a tradition of periodic publication of catalogs of holdings within a particular Order of vertebrates. These catalogs also include much taxonomic insight and sometimes revision, as well as important illustrations, and have value long after the specimen lists included are outdated. Lesser or regional collections are less appropriate for publication in this form of a combined catalog and taxonomic overview, and generally the holdings of such institutions are not publicized. Moreover, with the current plethora of museum collections with large and constantly expanding herpetological holdings, it would probably occupy an excessive proportion of publication budgets to publish comprehensive and constantly updated catalogs. A substitute means of promulgation of this information is clearly needed, and the recent efforts of J. Iverson (pers. comm.) to prepare a worldwide catalog of turtle specimens is to be applauded. Obviously, modern techniques employing computer terminals in each institution and a centralized data base hold great promise for facilitating the task of preparing complete lists of museum holdings, and efforts towards this are under way by the Association of Systematics Collections. Owners of private collections could cooperate by providing specimen lists to the curator of the institutional collection closest to them, or which has been identified as the permanent repository for the private collection in the future.

In my experience, it is incorrect to assume that all private collections are less accessible than all public collections. Owners of some important private collections deny access to other workers altogether, whilst others will even admit visitors at weekends or evenings, when public institutions are likely to be closed. Some institutional collections, although theoretically public, are fraught with idiosyncratic opening hours or access policies. In the extreme case, such collections may be only minimally public, being guarded jealously by curator/researchers who maintain them essentially as private collections subsidized with public money.

Most museum specimens in foreign countries are effectively inaccessible to workers without generous travel budgets. Mail service to many countries is so appalling that the average specimen would be unlikely to get home safely after a round trip through international mails. Thoughtful workers would not insist upon such a loan even if the institution were willing.

c) Owners of private collections do not typically keep them until death do them part, unless the owner should die young. Numerous circumstances — an unsympathetic spouse, space needed for a growing family or other reasons, changing interests, lack of time, or moving to a smaller residence or no longer having office space upon retirement, prompt owners of private collections to seek an institutional depository for them. It makes obvious sense for the ultimate recipient to be identified in the owner's will, although this perhaps should not be done too early in life since the owner may later make a career move to an institution that expects to incorporate his collection, and changes in the ultimate beneficiary, while obviously possible, can be awkward. Meanwhile, the intelligent strategy for curators of institutional collections is to adopt a friendly and cooperative attitude towards local owners of important private collections, on occasion perhaps providing them with supplies of preserving fluids or labels, urging them to draw up catalogs of specimens that can be kept on file at public institutions, and providing other forms of encouragement. The institution will eventually get the whole accumulation, at minimal expense to itself or the public purse.

The permanence of even public or institutional collections, incidentally, while earnestly to be sought, is not absolute. The major national collections in developed countries will presumably have a permanent existence, although World War II resulted in destruction of much important material in European collections, as well as the levelling of the Valetta (Malta) Museum and the total destruction of its display specimens (Brongersma and Carr 1983), but lesser collections, or those in politically unstable countries, can easily be closed down or just disappear, as was noted by Patterson (1936).

d) The curation of both public and private collections runs the gamut from meticulous to inadequate. There are rich and dedicated individuals and poor or sloppy institutions, and the reverse. Some university collections are well curated only so long as the individual who contributed most of the specimens remains on the faculty. Curation may subsequently lapse and it would have been better had the collection remained with the individual who assembled it.

It is possible that my personal collection to a degree reflects the same instincts that prompted me to collect stamps twenty years ago. However, it is also a necessity for a herpetologist with systematic and osteological interests, such as myself, who needs access to specimens and who does not live close to a major systematic collection. Whilst Oviedo, Florida, is not the depths of the Amazon, it is over 100 miles from the nearest major collection (the Florida State Museum), and it is not always convenient to make the journey there to check on a single specimen or a minor point. Moreover, just as non-directed browsing through books in a library sometimes yields treasures of information that could not have been obtained in a more systematic fashion (despite what the computer index enthusiasts may insist), so contemplation and handling of preserved and skeletal specimens may well result in new ideas, inspirations, or observations. Yet few public institutions, however well-intentioned, are able to accommodate significant numbers of visitors who just wish to "browse" in the research collections.

Nevertheless, I recommend that tenured and "settled" members of universities not become owners of major personal collections, since they can have them curated by the local university museum, with mutual benefits. Museum employees themselves would be in a conflict of interest situation with a home collection, unless they put a moratorium on new acquisitions at least for the duration of their employment. But an untenured or junior faculty employee who requires ongoing access to his own specimens may be excused for holding on to them. His next post may be thousands of miles away and he would naturally like to take them with him.

One advantage of a private collection is that the owner may conduct or authorize certain procedures, such as dissections, that are in general not permitted or are inappropriate for specimens in public collections. These may include permanent transfer of specimens to other collections. For example, during a visit from Dr. L. D. Brongersma some years ago, I learned that no European collection included a carapace of a mature Kemp's ridley *(Lepidochelys kempi)*. I was able to donate one to the Leiden collections on the spot from my own holdings of this species.

A collection of biological specimens does not typically include many items that could be considered "unique," with the limited exception of record-sized specimens. By this, I mean that the possession of a specimen by a private collector does not normally prevent a public collection from acquiring specimens that are functionally similar and just as useful. This may not be true in palaeontology or in collections of recently extinct organisms, but generally a private collection of biological specimens could be essentially duplicated by a public institution wishing to do so. Curiously, few raise objections to private art collections, even though an original sculpture or painting is truly unique, and private butterfly or shell collections are not considered offensive by most people even though they require sacrifice of sometimes rare specimens.

It is important to recognize more than one possible motive for depositing a specimen in any collection. One of these motives is that of providing a "voucher specimen" so that later workers can satisfy themselves that a specimen about which a certain morphological or distributional point was made in the literature was accurately identified (although of course it must be realized that a voucher specimen only allows one to confirm the identification of the specimen; one is still dependent upon the collector's word for the locality). Still, such voucher specimens belong in public institutions and serve little purpose in private collections. On the other hand, specimens kept primarily for studies of geographic variation (which need collecting data) or anatomy or morphology unrelated to geographic variation (when collecting data are less important) may reasonably be retained by a researcher if he can benefit from ongoing access to them.

Finally, private collectors, whether of stamps, shells, art, or turtles, often exhibit extraordinary zeal. With live turtles too, by far the most varied accumulations are in private hands rather than in zoos. The existence of private collectors thus adds greatly to the sum total of available material and, as mentioned above, patient and helpful curators of public institutions can expect to get it all in the end anyway.

I would welcome responses or opposing viewpoints.

TECHNIQUES

A COMBINED HOOK FOR HANDLING SMALL VENOMOUS SNAKES

There are many devices for handling venomous snakes and all have a double function: To prevent the handler from being bitten and to avoid injury to the snake. Several satisfactory instruments for handling adult venomous snakes have been reported (Gillingham et al. 1983; Freed and Freed 1983; King and Duvall 1984; Fuhrman 1975). However, devices for handling juvenile or smaller species of venomous snakes have not been reported. This paper describes a new, combined hook that was developed for handling newborn and/or small-bodied venomous snakes under laboratory conditions.

The tool (Fig. 1) is constructed by modifying a steel fencing foil and consists of three main parts:

1. The "hook end": This part is flattened and curved so that it is easy to insert under the body for elevation of the specimen.

2. The "body": Behind the hook is a straight cylindrical section, covered with rubber tubing. This portion is used to gently press the snake's head onto the substrate before grasping by hand.

3. The "oar end": This part is flattened and resembles a small oar having a double-angled neck. Its function is to lift the snake's neck up between the fingers during the grasping process (Fig. 2). This is important because it is often difficult to pick up a small snake with the fingers.

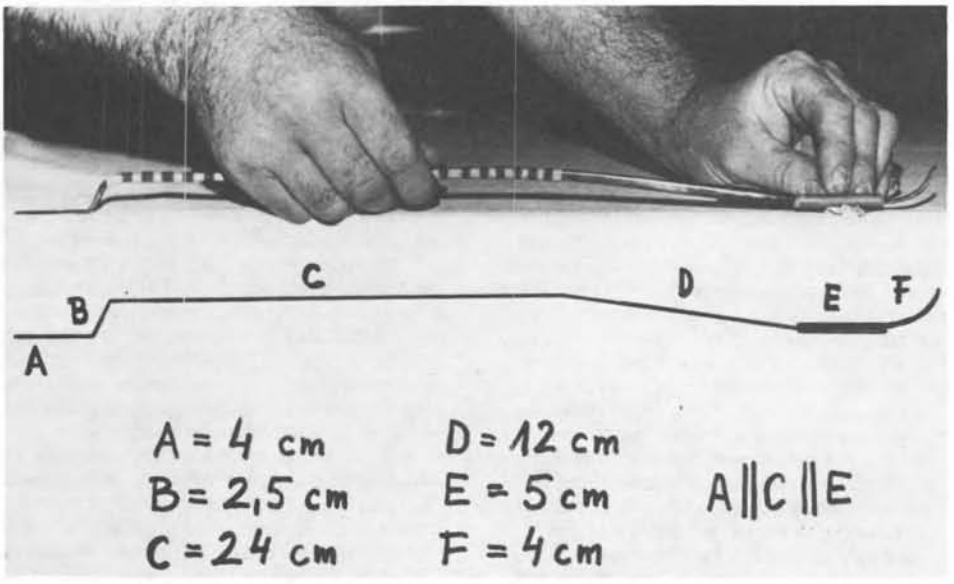

Figure 1. Overall view and dimensions of the snake hook. The snake's head is immobilized by pressing with part of the tool covered by rubber tubing.

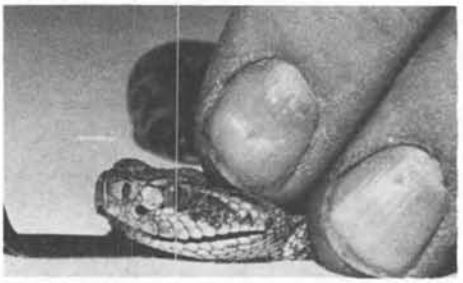

Figure 2. The oar end is slipped under the head-neck region of the snake, as the latter is pressed down between the fingers.

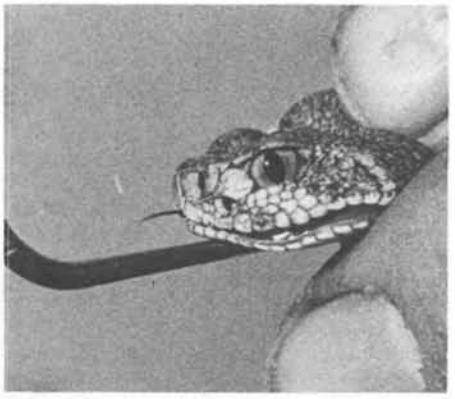

Figure 3. After slight release of pressure on the neck, the snake can be raised so a firmer grip can be applied on the neck and head.

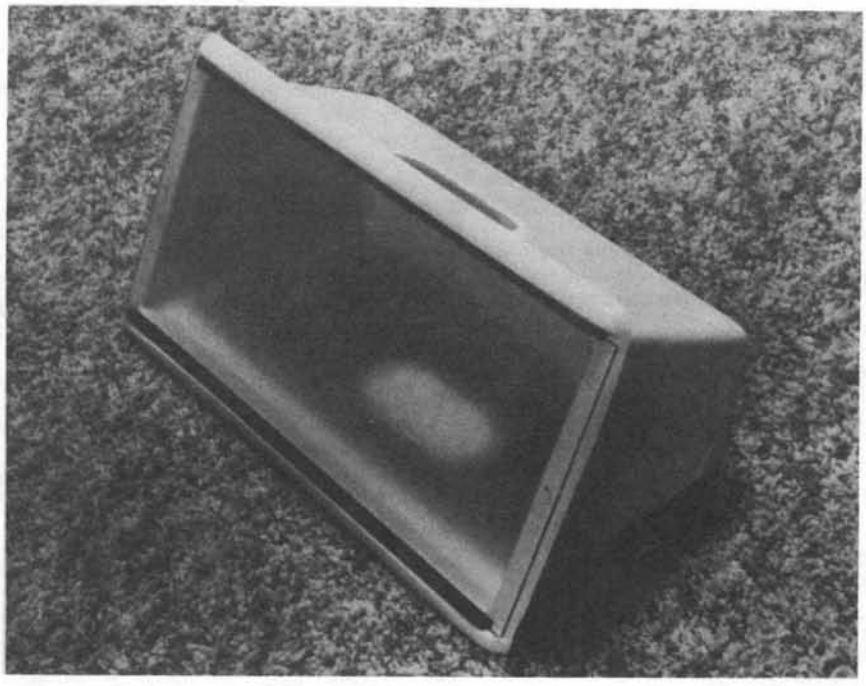
After immobilizing the snake with the rubber-covered section, the "oar" is used to lift the head into a better position between the

Ecology and Natural History of Desert Lizards

Analyses of the Ecological Niche and Community Structure

Princeton University Press
41 William Street, Princeton, NJ 08540



Eric R. Pianka

Eric Pianka offers a synthesis of his life's work on the comparative ecology of lizard assemblages in the Great Basin, Mojave, and Sonoran deserts of western North America, the Kalahari semi-desert of southern Africa, and the Great Victoria desert of Western Australia. Prior to his efforts, lizard ecology in these areas was virtually uninvestigated. In Australia he discovered half a dozen new species, as well as the richest lizard faunas known. Perhaps the single most important aspect of his research is the fact that he has described three comparable but independently evolved ecological systems. Study of such widely spaced systems by a single researcher using identical field techniques provides unique material for understanding questions of community structure and ecological convergence.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

fingers (Fig. 3). This makes it unnecessary to grasp the snake with fingernails or fingertips or having to exert too great a force in the process. Pressing the soft tissues of the neck against the vertebrae could easily result in trauma.

The various angles of the tool are important in providing comfort and balance. During the whole procedure, the longest section of the tool is gripped. While pressing down the snake's head or slipping the oar under the head, the end being used should be parallel to the substrate. At the same time, the articulations of the hook-grasping fingers should also contact the substrate, providing easier coordination of the tool and greater control over the degree of pressure being applied to the snake's head (Fig. 1).

ACKNOWLEDGMENTS

Special thanks go to my colleague Dr. Ernó Vértes for taking the photographs.

A NEW METHOD FOR COLLECTING AQUATIC LARVAL SALAMANDERS

Aquatic larvae of many species of salamanders inhabit streams with rocky, irregular bottoms. Collecting larvae from these streams is often difficult and time consuming. Larvae have traditionally been collected from rocky streams by a combination of hand-grabs and small nets; however, larvae frequently are located in areas that prevent collecting by hand-grabs and the irregular bottom reduces the effectiveness of nets. During the last 25 years I have developed some degree of proficiency collecting salamander larvae by these methods, but I can rarely capture more than 60% of the larvae I locate. In the mountain streams of Virginia 1-2 hours is often required to obtain a sample of 25 *Eurycea* larvae. Because many larvae escape collection the possibility of a sample bias exists when using hand-grabs and nets as collection methods.

I have devised an apparatus that allows capture of over 90% of larvae sighted. The time required for collecting larvae is less than one-half of that required to collect them by traditional techniques. The apparatus consists of a 150 ml rubber pipetting bulb with a 40 cm length of 15 mm diameter clear flexible tubing inserted into the bulb opening.

After sighting a larva in the stream, I squeeze the bulb and place the open end of the tube near the larva and quickly release the pressure on the bulb. The larva is sucked into the tube. The larva may be observed and measured in the tube. It may then be released into the stream or squirted into a container by squeezing the bulb. I have collected over 600 individual larvae using this technique. Many of these have been recaptured several times, and I have not observed any trauma to the larvae. This technique is very successful not only in collecting larvae that are visible to the collector, but also for sucking larvae from under rocks and from crevices even if they can not be seen. Placing the clear tube near larvae does not cause them to move to another position in the stream. The size of the tube can be altered to meet the needs of the individual collector. Bulbs smaller than 150 ml do not suck sufficient water into the tube to be effective and bulbs larger than 200 ml are cumbersome and unnecessary. However, if the size of the tube is modified it may be necessary to alter the size of the bulb.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, USA.

ANURA

RANA CATESBEIANA (Bullfrog). **PREDATION.** Bullfrogs are known to be preyed upon by some birds (Chapin 1908. Proc. Staten Isl. Assoc. Arts Sci. 2:3-8; Jenni 1969. Ecol. Monogr. 39:245-270; Niethammer and Kaiser 1983. Colonial Waterbirds 6:148-153). Although infrequent reports exist of terns of the genus *Chlidonias* taking frogs (Craig 1974. Ostrich 45:142) or their life stages (Pandit 1982. Indian J. Ecol. 9:181-190), to our knowledge, the only report of any member of the tern genus *Sterna* taking frogs is that of Peabody (1896. Osprey 1:1-3, 21-23) of Forster's terns *(Sterna forsteri)* from Heron Lake, Minnesota consuming unidentified dead frogs and feeding unidentified live frogs to their young. Here we report predation by Caspian terns *(Sterna caspia)* on postmetamorphic *Rana catesbeiana.*

In the course of a study of a nesting colony of Elegant Terns *(Sterna elegans)* on dikes separating salt evaporating ponds at the south end of San Diego Bay, California during 1980 and 1981, one of us (FCS) made several observations that indicated predation on bullfrogs by *Sterna caspia.* On 9 June 1980, a dead *Sterna caspia* chick was found with a bullfrog missing a left hind leg in its throat. On 6 May 1981, an adult *Sterna caspia* was observed flying overhead with a subadult *Rana catesbeiana* (ca. 80-90 mm SVL) in its bill. Furthermore, on 20 May 1980, one pair of bullfrog legs severed just above the pelvis was found in a *Sterna caspia* nest.

These observations suggest non-incidental predation by *Sterna caspia* on postmetamorphic *Rana catesbeiana.* The observations indicate that bullfrogs were exploited as food during tern reproduction. It is also noteworthy that the *Sterna caspia* population at San Diego was not established until ca. 1940 (Gill and Mewaldt 1983. Auk 100:369-381) and that bullfrogs did not become well-established until about this time (Jennings and Hayes 1985. Herpetologica 41:94-103).

SAURIA

AGAMA AGAMA (Common agama). **EGG LAYING.** Three female *Agama agama* were observed laying eggs at Niono (14° N, 6° W) in central Mali on 19 July 1980. This lizard is by far the commonest reptile in the area. The eggs were laid in sand two days after heavy rain had fallen. Activity started at 1300 h, in sunshine. The temperature was 35.3° C and humidity was 92%. Each female made a separate nest ca. 1-3 m apart. The female at nest 1 was active for 58 minutes during this time and laid 13 eggs. Female 2 was active for 84 minutes, was interrupted by and copulated with a male on several occasions during the period and laid 11 eggs. Female 3 was intermittently active over 38 minutes, was courted by the male, but did not lay any eggs. At nest 1 the female dug the nest with her front legs and evacuated the soil with her hind legs. She then laid her eggs from a rather upright stance with the head thrust upwards. Sand was dragged in with the fore legs and consolidated with both fore and hind legs. Further eggs were then laid and the covering and consolidation activities were repeated. The nest was finally smoothed over and considerable time was spent scarifying the sand surface about 30 cm away from the nest. The deepest egg was at 180 mm below ground level and the shallowest at 50 mm. Mean measurement of four eggs was 14.37 x 9.02 mm and mean mass was 0.94 g.

SERPENTES

AGKISTRODON CONTORTRIX PICTIGASTER (Trans-Pecos Copperhead). **FEEDING.** The feeding behavior and prey items of *Agkistrodon contortrix* are well documented in general, but little has been recorded for the westernmost subspecies. *Agkistrodon contortrix pictigaster* is known to consume small rodents, lizards, frogs, toads and insects (Tennant 1984. The Snakes of Texas, Texas Monthly Press, 561 pp). Tennant (ibid) also states that *pictigaster* probably eats birds and lists the only recorded instance of ophiophagy *(Crotalus lepidus).* Herein, we list a second instance of ophiophagy and verify Tennant's assumption of birds in the diet of *A. c. pictigaster.*

At 2145 h on 20 July 1983, an adult female *A. c. pictigaster* was found in the process of consuming a *Rhinocheilus lecontei tessellatus* (Texas long-nosed snake). The copperhead was approximately 60 cm off the pavement of highway 163, 78.9 km south of the town of Ozona, Crockett Co., Texas. All but the tail and posterior few cm of the long-nosed snake had been consumed. The copperhead completely ignored the observers' presence, even submitting to measurement without ceasing consumption of the *Rhinocheilus.* The copperhead measured 65 cm TL. It was estimated that the *Rhinocheilus* measured 42-47 cm TL. The ground was still damp from an afternoon thunderstorm and the air temperature at the time of observation was 26° C.

It was not known whether the *Rhinocheilus* had been hit by a car prior to consumption or if the copperhead had caught and killed it. There was blood on the road not far from where the snakes were discovered, and considerable blood around the vent of the *Rhinocheilus* and on the ground in the immediate vicinity of the snakes. We have often observed *R. l. tessellatus* to void blood from the cloaca when captured. The copperhead may have found and dragged the *Rhinocheilus* off the road.

At 2315 h on 11 June 1985, an adult male *A. c. pictigaster* was found under a shrub at the base of the canyon wall at Arch camp, on the U.S. side of the Rio Grande, several km inside Santa Elena Canyon, Brewster Co., Texas. Upon discovery, the copperhead started to flee, but it then momentarily paused before it turned and crawled back through the shrub for about 0.5 m to where it found and started eating a nestling cliff swallow *(Petrochelidon pyrrhonota).* The snake completely ignored the observers' presence, consumed the baby bird in a few minutes and then took refuge in a crevice in the canyon wall. The snake was approximately 50 cm TL.

Cliff swallows nest on the sheer 300-350 m high limestone walls along both sides of the canyon. Most of the nests visible in the immediate vicinity of Arch camp were, however, across the river on the Mexican side, and the nestling swallow that the copperhead had consumed was much too young to fly.

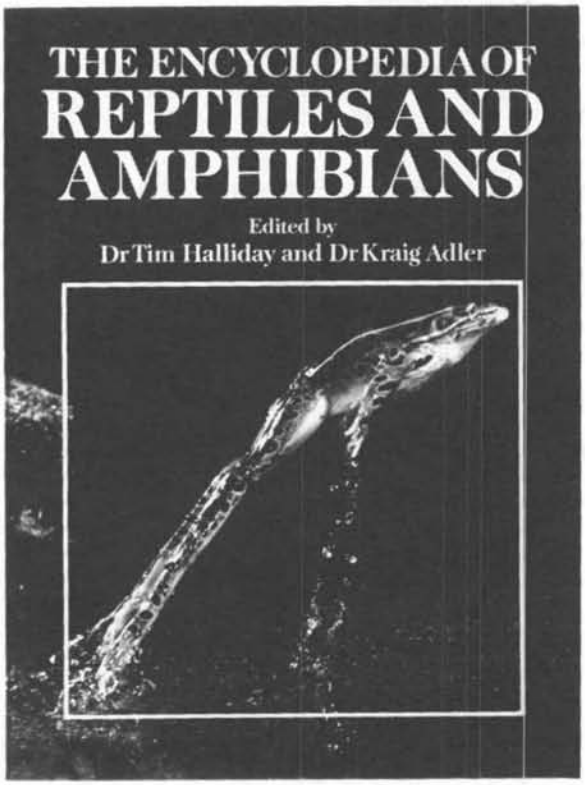
The following morning, Chihuahuan ravens *(Corvus cryptoleucus)* were observed raiding the swallow nests, pulling the nestlings out and flying off with them. Occasionally, they would drop the nestlings, apparently trying to kill them. Several were observed being dropped that were not recovered, some of which landed well up on the bank of the U.S. side of the river. We believe the copperhead consumed a nestling that had been dropped by one of the marauding ravens earlier in the day. This apparent opportunistic feeding is of special interest because competition for food at Arch camp must be high due to the isolation of the location and the large population of copperheads found there.

We thank Roger Conant for his thoughtful comments on the manuscript.

Submitted by **HUGH K. McCRYSTAL,** Arizona-Sonora Desert Museum, Rt. 9, Box 900, Tucson, Arizona 85743 and **RICK J. GREEN,** P.O. Box 146, Terlingua, Texas 79852, USA

NAJA MELANOLEUCA (African Forest Cobra). **CAUDAL USE.** A moderate number of snake species are known to possess a relatively sharp spine on the tip of the tail; suggested functions of such a caudal tip have been as an aid in burrowing, prey-handling, and in defense as a possible mechanism for facilitating escape from a predator. Carpenter and Ferguson (1977. pp. 335-554, *In*: C. Gans and D. W. Tinkle, eds. Biology of the Reptilia. Vol. 7) listed eleven species in four families (Typhlopidae, Aniliidae, Colubridae, Viperidae) that have been reported to use this caudal adaptation as a mechanism for defense. With the exception of a single venomous species, *Atractaspis bibroni,* all are considered inoffensive, fossorial, and in some cases nocturnal, forms. This note describes caudal use in a high-profile elapid species, *Naja melanoleuca.*

A sexual pair of newly hatched *N. melanoleuca* was received in April, 1984. Both specimens were restrained anteriorly in a clear plastic tube on 22 February 1985 and again on 14 May 1986 for sex determination. Once in the tube, the snakes were grasped at midbody with one hand and at the region of the vent with the other.



In all cases, both responded with a rapid side to side motion of the tail which was accompanied by repeated, vigorous jabbing of the caudal tip against the hand and wrist. This action was forceful enough to superficially scratch but not penetrate the skin. Jabbing behavior increased in intensity as the caudal grip on the snakes was slowly moved posterior to the vent region. During these sequences, both specimens attempted to maneuver backward using the entire tail, tip first, to encircle the hand and wrist. This latter behavior has been noted when specimens were suspended by the tail from handling equipment and exhibit props.

Naja melanoleuca, a large and dangerous elapid species, would not seem to "need" a sharp tail tip for defense, though it may be effective as such against some predators. Based upon this species' ability to gain a secure hold on objects using only a small portion of the entire tail, we feel that another function may be associated with its arboreal tendencies.

Submitted by **BERN W. TRYON** and **JON WHITEHEAD,** Department of Herpetology, Knoxville Zoological Park, P.O. Box 6040, Knoxville, Tennessee 37914, USA

NERODIA SIPEDON (Northern Water Snake). **FEEDING.** At ca. 1500 h on 26 April 1986 a small *Nerodia sipedon* (33.1 cm TL) was collected from a small limestone stream in Raven Run Nature Preserve in Fayette Co., Kentucky. The snake was collected to determine if it had been preying on *Ambystoma texanum* larvae which were abundant in the stream. Upon returning to the laboratory one hour later I examined the plastic bag and found the snake had regurgitated three partially digested *A. texanum* larvae (1.9, 1.8, 2.4 cm TL) and a live and apparently unhurt *Pseudotriton montanus* larva (7.8 cm TL). The significance of *A. texanum* larvae in the diet of *Nerodia sipedon* from this stream is unknown (J. Petranka, pers. comm.). Examination of the *P. montanus* larva under a dissecting scope revealed only a slight abrasion to the animal's tail. The larva transformed within two weeks of captivity. Although *N. sipedon* apparently commonly feed on *P. montanus* (Brown 1979. Brimleyana 1:113-124) this instance was unusual because of the regurgitation of a live animal and because records for *P. montanus* larvae are relatively rare in the Inner Bluegrass of Kentucky.

I would like to thank J. Holomuzki for commenting on the manuscript. Both the *N. sipedon* and the *P. montanus* will be depos-

ENCYCLOPEDIA OF REPTILES AND AMPHIBIANS

DR. TIM HALLIDAY
DR. KRAIG ADLER
Editors

"Contributions of 19 internationally recognized authorities, including editors Halliday and Adler, provide the taxonomically-ordered text sections of this encyclopedia. Current summaries of taxa above the species level emphasize numerous aspects of herpetozoan morphology, evolution, reproduction, classification, distribution, ecology, folklore, and natural history. Well-chosen examples at the species level add considerably to the depth of coverage and to reader appeal...The volume's attractiveness is increased immensely by the abundant and superb artwork panels of David M. Dennis and Michael R. Long... Highly recommended."—*Choice*

Nineteen experts advance a complete and definitive survey of these two classes of animals, once the dominant life-forms on Earth. The contributors include such world-renowned authorities as Carl Gans, The University of Michigan at Ann Arbor, Alan Charig, The British Museum, Marvalee H. Wake, University of California, Berkeley, and George Zug, National Museum of Natural History, Smithsonian Institute.

The ENCYCLOPEDIA OF REPTILES AND AMPHIBIANS covers every family of these animals: • snakes • frogs & toads • lizards • tuatara • salamanders & newts • worm lizards • caecilians • turtles & tortoises • crocodiles and alligators

The text is complemented by more than 150 full-color photographs and illustrations. In addition, there are 70 maps to indicate principal habitats. A wealth of fast, incisive, information for every biologist, herpetologist, and naturalist, professional and amateur alike.

160 pp. 8½ X 11. $24.95.

An Important New Book

INTRODUCTION TO THE HERPETOFAUNA OF COSTA RICA
INTRODUCCION A LA HERPETOFAUNA DE COSTA RICA

by JAY M. SAVAGE & JAIME VILLA R.

About 250 pages, 15 figures including a map, 8 1/2 by 11 inches, clothbound. To be published December 1986.

THE BOOK. The Costa Rican herpetofauna is one of the largest and most diverse in the world and this new book is the first to cover comprehensively all of the species of amphibians and reptiles native to Costa Rica. Because extensive field work and systematic studies have been carried out recently in Costa Rica, its herpetofauna is the best known of any country in the Neotropics.

This book is both in English and in Spanish. There is a checklist that also gives the range for each species. The major portion of the text is comprised of illustrated keys to the genera and species, and separate keys to tadpoles and to poisonous and non-poisonous coral snakes. There is an extensive annotated bibliography, a bibliographic index, a separate index to published illustrations of tadpoles, and a comprehensive index.

THE AUTHORS. Jay M. Savage is Professor of Biology and Chairman of the Department of Biology at the University of Miami and head of the university's Program in Tropical Biology. Together with his many students and associates, Professor Savage has conducted field work and systematic studies on the amphibians and reptiles of Costa Rica for over 25 years and is the acknowledged authority on the Costa Rican herpetofauna.

Jaime Villa R., Associate Professor of Biology at the University of Missouri, Kansas City, is the leading expert on the lower vertebrates of neighboring Nicaragua and the author of books on the poisonous snakes, amphibians, and fishes of that country. He has had extensive field experience throughout Central America, including Costa Rica.

Now Published

THE TURTLES OF VENEZUELA
by Peter C. H. Pritchard & Pedro Trebbau

1984. 414 pages, 48 color plates (25 watercolor portraits and 165 photographs of turtles and their habitats), 16 maps, 8 1/2 by 11 inches, bound. Covers the systematics, life history, and distribution of 22 species, half of the turtle species found on the South American continent. A detailed four-page color prospectus is available on request.

From recent reviews:

"An unprecedented accomplishment as a comprehensive summary and review of a segment of the South American turtle fauna." J. Whitfield Gibbons, *Quarterly Review of Biology*

"This handsome volume . . . should be purchased by everyone interested in turtles. The authors have provided more . . . detail than any previous single volume on the systematics of turtles. The cliche 'mine of information' is here wholly justified. The color paintings . . . are glorious, comparable to the best 19th century animal illustrations and are by themselves a reason for owning the book." Ernest E. Williams, *Herpetological Review*

"The first monograph on the turtle fauna of a South American country, and it delivers considerably more than one would have expected from the title alone. It combines the highest standards of a reference work with the aesthetic qualities of a modern field guide. The book is a major milestone in its field." Wolfgang Böhme, *Salamandra*

ORDERING INFORMATION. Orders should be sent to Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR." Prices include shipping charges (book rate) within USA; all overseas orders will be billed only for the *additional* postage charges. Publications sent at customer's risk; however, packages can be insured at customer's cost. Overseas customers must make payment in USA funds, by International Money Order, or by MasterCard or VISA (in which case account number and expiration date must be provided). A complete pricelist and information on Society membership are available on request from Dr. Taylor.

TESTUDINES

CLAUDIUS ANGUSTATUS (Chopontil). **COLORATION.** Albino turtles have been reported for several genera of turtles *(Chrysemys, Clemmys, Pseudemys, Terrapene, Gopherus,* and *Chelydra)* in the families Emydidae, Testudinidae, and Chelydridae. (Dyrkacz 1981. SSAR Herpetol. Circ. No. 11:1-31; Gilboa and Dowling 1974. HISS Publ. Herp. 6:1-11; Hensley 1959. Publ. Mus. Mich. State Univ. Biol. Serv. 1:133-159.) This is the first reported albino for this genus and for the family Staurotypidae.

On 29 November 1983, 80 female *Claudius* containing shelled eggs were collected in the pantanos 2.3 km north of Lerdo de Tejada, Veracruz, Mexico. They were injected on 12 December with oxytocin, 1 unit per 100 g body weight, to induce oviposition. A total of 229 eggs were laid; 1-5 ($\bar{X}$ = 2.8) eggs per clutch. Half of each clutch was incubated at 29° C and the other half at 25° C in a mixture of water-vermiculite at a ratio of 1:1 by weight in a sealed clear plastic bag. On 24 June 1984, after 194 days of incubation, the albino pipped from an egg incubated at 25° C. As hydric conditions often cause the eggs of Kinosternids and Staurotypid turtles to crack longitudinally months before the embryo is completely developed, pipping is defined as when the hatchling begins biting its way out of the egg. The egg measured 28.9 x 17.5 mm with a mass of 5.5 g. The other egg from this clutch died during the early stages of development, as did most other eggs incubated at 29° C. A total of 72 *Claudius* hatched from this series of eggs, but no others had abnormal color patterns. The albino lived in captivity for 7 months, and now has been deposited in the collection here (3019 UNAM-LT).

Submitted by **RICHARD C. VOGT,** Estacion de Biologia Tropical "Los Tuxtlas," Instituto de Biologia, Universidad Nacional Autonoma de Mexico, Apt. Post 94, San Andres Tuxtla, Veracruz, Mexico. ●

GOPHERUS POLYPHEMUS (Gopher Tortoise). **BURROW COMMENSALS.** A survey of amphibians and reptiles associated with burrows of *Gopherus polyphemus* was conducted on a 14-hectare section of the Smith Lake Sandhill Site on the Katharine Ordway Preserve-Carl S. Swisher Memorial Sanctuary, 4 km SE of Melrose, Putnam Co., Florida. The study area included approximately 45 active, inactive and old tortoise burrows in a high pine-scrub oak forest environment.

Animals were captured in single-opening screen funnel traps set flush with the burrow opening. Traps were installed ca. 1-2 hours before sunset and retrieved the next morning 1-2 hours after sunrise. As tortoises are primarily diurnal, I felt that this schedule would reduce injury to trapped animals by the movements of resident tortoises. Traps were set on 62 days between September 1983 and October 1985 for a total of 2551 trap nights (=one trap/burrow/night).

The following amphibians and reptiles were captured: 313 *Rana areolata aesopus,* 24 *Cnemidophorus s. sexlineatus,* 16 *Eumeces inexpectatus,* 12 *Sceloporus u. undulatus,* 8 *Anolis c. carolinensis,* 4 *Scincella laterale,* 3 *Crotalus adamanteus,* 3 *Gastrophryne carolinensis,* 2 *Masticophis f. flagellum,* 2 *Pituophis melanoleucus mugitus,* 2 *Heterodon platyrhinos,* 2 *Cemophora c. coccinea,* 2 *Elaphe g. guttata,* 2 *Thamnophis s. sirtalis,* 2 *Micrurus f. fulvius,* 2 *Eumeces egregius onocrepis,* 2 *Bufo terrestris,* 1 *Drymarchon corais couperi,* 1 *Acris gryllus dorsalis.* This computation includes trapping data for 582 trap nights presented in Table 7 of Humphrey, Eisenberg, and Franz (1985. Wildl. Soc. Bull. 13:487-496).

A total of 403 individuals representing 19 amphibian and reptile species were captured. These data suggest that burrows are not just residences for tortoises, but are also important retreats for a variety of other upland amphibians and reptiles. Thus, we could expect that with the continued decline in the number of gopher tortoises in the southeastern United States we might also see changes in populations of other sandhill amphibians, reptiles, and other wildlife which frequent their burrows.

PSEUDEMYS FLORIDANA PENINSULARIS (Peninsula Cooter). **EGG PREDATION.** Sixteen viable nests and 102 predated nests of *Pseudemys floridana peninsularis* were investigated between November 1983 and March 1986 on the Katharine Ordway Preserve-Carl S. Swisher Memorial Sanctuary, 4 km SE of Melrose, Putnam Co., Florida. Nests were found in xeric live oak forests (=hammocks) and longleaf pine-scrub oak forests, 50 to 200 m from ponds and lakes. Nest sites were typically constructed in open patches of sand, particularly along sand roads. One hundred and eight nests were found from November-May.

Viable nests were discovered while females were still at nest sites. Fourteen of these nests were constructed in the manner described by Carr (1952. Handbook of Turtles, Cornell Univ. Press, Ithaca, p. 294) with a deep central chamber and two shallow satellite pockets (with 1-3 eggs per hole, but not exceeding 4 eggs in total). Two nests had only one satellite chamber each.

Depth of central chambers $\bar{X}$=12.5 cm; side pockets, $\bar{X}$=6.0 cm. Eggs in central chambers were covered with $\bar{X}$=5.0 cm of soil; eggs in satellites had 2.0 cm of covering. At one nest site, the shell of an egg in a satellite pocket was covered with only a thin layer of sand, allowing it to be visible from above.

Destroyed nests were obvious from the excavations left by egg predators and from scattered egg shells. Footprints and the nature of the excavation suggested that raccoons *(Procyon lotor)* were responsible for all of the destruction.

Ninety-nine of the predated nests were constructed as described above. The three other nests were aberrant (two with a central chamber and one satellite hole, and the third with apparently no side holes). Only two predated nests contained eggs after the egg predator had left the site, but, in each case, we suspect that we may have frightened away the raccoon before it had a chance to finish. The overlooked eggs occurred in only the central chambers.

Carr (op. cit.) speculated over whether this nesting behavior may reduce predation by

1986 HERPETOLOGICAL CIRCULAR
No. 15
CANNIBALISM IN REPTILES: A WORLD WIDE REVIEW
by
JOSEPH C. MITCHELL

The 1986 Herpetological Circular is a comprehensive compilation of records of the occurrence of cannibalism in reptiles. It includes a review of literature, a discussion of the terminology and its problems and a listing of 192 species accounts, with information on prey size, sex of the individuals involved, whether the incident was in the field or in a captive situation, and other ecologically relevant data. It is an important volume for all interested in the subject of cannibalism.

TRIONYX SPINIFERUS (Spiny Softshell Turtle). **SIZE.** A possible record size for an undetermined subspecies of *Trionyx spiniferus* was exhibited by a female specimen captured 4 October 1985 in Ouachita Parish, Louisiana. The specimen, possessing a deep camouflage pattern on the carapace typical of old females, had an impressive mass of 11.7 kg and possessed the following morphometry: carapace length = 54.0 cm, carapace width at widest point = 40.6 cm, plastron length = 36.2 cm, and tail length = 22.2 cm. The female was taken in 1.5 m of water by a 0.91 m diameter hoop net in a paper plant impoundment, Wham Brake, located approximately 16 km NE of Monroe, Louisiana off the south shoreline about 1.6 km W of the spillway. Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) listed the upper limit in carapace length for *T. spiniferus* as 18 in (46 cm) and Lagler (1943 Amer. Mid. Nat. 29:257-312) mentioned "more than 16 in (40.6 cm)" as maximum size.

Subspecies designation was not assigned to the large female *Trionyx* because of physical changes associated with age, sex, and intergradation. In Mississippi, Arkansas, and Louisiana there are intergraded populations of *T. spiniferus* that have characteristics of the three subspecies, *harwegi, spiniferus,* and *aspera* (Carr 1952. Handbook of Turtles, Comstock, Ithaca.).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

BUFO MICROSCAPHUS (Southwestern Toad). USA: NEW MEXICO: Sierra Co: 35 km E Beaverhead on NM 59, T10S R10W S 11. 12 July 1969. W. G. Degenhardt. BOOK REVIEWS

Anfibios de los Alrededores de Buenos Aires, by J. M. Gallardo, EUDEBA (Ed. Universitaria Buenos Aires), 229 pp., 3 fig., 16 pls., 1974.

Reptiles de los Alrededores de Buenos Aires, by J. M. Gallardo, EUDEBA (Ed. Universitaria Buenos Aires), 213 pp., 3 fig., 16 pls., 1977. (EUDEBA, Rivadavia 1571/73, Cap. Fed., Buenos Aires, Argentina).

Qué Sabe Usted de Víboras?, by J. W. Abalos, Ed. Losada, B. Aires, 174 pp., 91 figs., 1977. (Ed. Losada, Alsina 1131, Cap. Fed., Buenos Aires, Argentina).

Interest in the South American herpetofauna is certainly increasing and new books have been published in the last few years, among them Duellman's THE SOUTH AMERICAN HERPETOFAUNA, 1979, and Cei's AMPHIBIANS OF ARGENTINA, 1980. Three additional books dealing with the temperate Neotropical herps, although published several years ago, seem to have been overlooked by many herpetologists. The three are popular accounts but differ in their format.

The first two books describe the herpetofauna of the Buenos Aires Province, Argentina. Although this area is commonly associated with the large Pampas plains, the landscape varies, ranging from hilly systems in the south to subtropical gallery forests bordering the Paraná River mouth in the north. They were written by the well known Argentinian herpetologist, Dr. J. M. Gallardo, for many years Director of the Argentinian Museum of Natural Sciences.

AMPHIBIANS OF BUENOS AIRES is divided into 8 chapters. The first two are an introduction to morphology, biology and landscapes of the area. The remaining chapters cover 19 species in five families (Bufonidae, Leptodactylidae, Pseudidae, Hylidae and Microhylidae). In some cases the descriptions are very detailed while in others some aspects of reproduction or ecology are stressed, following Gallardo's extensive work on these subjects. Some interesting chapters include one devoted to the Pseudidae frogs, of which the author still continues to be the latest reviewer, and a reprint of his study on *Bufo granulosus* complex distribution and hydrographic basins (but see Cei 1980 for nomenclature). The book is softcover, it includes 3 diagrams in text and 16 central black and white plates with photos of 15 species.

REPTILES OF BUENOS AIRES follows the same pattern, including introductory chapters, and consideration of the principal groups in subsequent chapters (Turtles, Crocodiles, Lizards, Amphisbaenian and Snakes). About 44 species are described and/or commented on in eight chapters, ranging from their description to diverse information on natural history. The main focus is on amphisbaenians, lizards (families Gekkonidae, Iguanidae, Teiidae, Scincidae and Anguidae) and snakes (families Leptotyphlopidae, Boidae, Colubridae, Elapidae and Viperidae). The descriptions of some Iguanid species are very detailed following the author's research on the group. The book is softcover, with three diagrams in the text and 16 black and white plates with photos of 16 species.

Both books are very similar in that they resemble collections of papers from journals, most of them Latin American. Introductory notes to each chapter (i.e. paper) are very short. As papers come from diverse sources with different purposes, not all species are considered with the same detail (in some accounts the morphological description is stressed, in others the biology) and reading does not go smoothly from chapter to chapter. Also, nomenclature has not been revised since publication of the original paper. In a number of instances the experimental results of some herpetologists, particularly North American, were not cited. Although I do not support this, I must say that the reverse also occurs, and more frequently: North American reviewers ignoring papers in Spanish and published in Latin America.

Gallardo's books contain much information that will be of great interest to herpetologists interested in the Argentinian herpetofauna. Although they were prepared for the public at large, they would be difficult for the beginner. But I would recommend these books for those who have difficulty obtaining the original papers or for those with research interests in the herps of the area.

The third book, by the late J. W. Abalos, is completely different. Abalos was a biologist at the Universities of Tucumán and Córdoba, Argentina, and his interest ranged from venomous spiders to snakes. On the other hand, he was also a popular writer and author of several fictional works.

Abalos' WHAT DO YOU KNOW ABOUT SNAKES? is restricted to Argentinian snakes. It has 15 chapters, covering basic information on morphology (particularly dentition) and biology (particularly reproduction, feeding and defensive behavior, etc.), with short stories and tales intercalated. The biological information stresses boids (particularly *Boa constrictor*), some colubrids and venomous snakes (*Micrurus, Bothrops* and *Crotalus*). Of particular interest is the description of *Clelia clelia* ("terciopelo") feeding on rattlesnakes. South American crotaline response to the "terciopelo" resembles North American rattlesnakes' behavioral response to kingsnakes. Abalos also published a note on this behavior (Abalos and Náder 1968) but this was not cited in the latest description of this behavior (Carpenter and Gillingham 1975; Weldon and Burghardt 1979). There are many black and white photos and diagrams, most of them of poor quality. An Appendix includes a list of Argentinian snakes (with common and scientific names) after Abalos and Mischis (1975). There are nomenclatural errors and many old names are retained in the main text.

In spite of these limitations this is a very good popular book on snakes in a strict sense: it was written for readers with almost no knowledge of snakes, avoiding an overabundance of information, and with many nice tales and anecdotes. It follows Abalos' literary works, containing delicious field stories (most notably TERCIOPELO, THE BLACK HUNTER, SHUNKO, SHALACOS, etc.). I would recommend this book for those that may read Spanish fluently.

FOR SALE

HERPETOLOGICA Volumes 1-41, 1936-1985. Includes the two separately published indices for the years 1936-1955 and 1956-1957.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES Accounts 1-390.2, 1963-1985. Includes two SSAR imprinted post binders.

HERPETOLOGICAL REVIEW Volumes 1-16, 1967-1985.

All are complete sets from my personal library and are in good, clean condition throughout. Price: $750.00 shipment prepaid and insured.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1986

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

SSAR TRANSLATIONS PROJECT

The object of this project is to make available to SSAR members accurate translations of foreign language research articles. Since SSAR has not budgeted money for translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy (or reprint) of the original and the translation to the coordinator. A few people have volunteered to translate articles and we are interested in hearing from any others who are willing to contribute their time.

If you have an article for translation that you feel would appeal to a large segment of the herpetological community, send a copy or reprint and we will try to have it translated. We now have a total of 99 translations available through the Translations Project. The titles of 31 are listed below. Previous titles appeared in *Herpetological Review* 10(3):82-83, 1979; 13(4):111-112, 1982; and 16(1):2-3, 1985. Copies of these are available (.06/page plus postage) from the Translations Project Coordinator, Robert D. Aldridge, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103, U.S.A.

I would like to thank Paul Gritis, Field Museum of Natural History, Chicago, IL and Margaret Berson, California Academy of Sciences, San Francisco, CA for their help in translating and providing articles for this Project.

NEWSNOTES

NIXON GRIFFIS FUND FOR ZOOLOGICAL RESEARCH AWARDS GRANTS

The Nixon Griffis Fund for Zoological Research (NGFZR), established in 1984 by New York Zoological Society Trustee Nixon Griffis, awarded ten research grants on 17 March 1986. One recipient was R. Andrew Odum, Houston Zoological Gardens for the "Aruba Island rattlesnake Species Survival Plan Conservation program."

Nixon Griffis Fund for Zoological Research grants are available to members of the zoo and aquarium community. Fund recipients may be keepers, curators, veterinarians, or research and consulting biologists. Grants, not to exceed $3000, are awarded semi-annually. Closing periods are January 1st and July 1st. For information about the Fund and grant application procedures, contact:

John Behler, Coordinator
Nixon Griffis Fund

SLIDE PROGRAM ON NEVADA'S HERPS AVAILABLE

A high quality color slide program depicting the herpetofauna of the Silver State is available from the Nevada Chapter of The Wildlife Society. The program, entitled *Silver Amphibians and Reptiles*, is assembled in a binder containing: written narrative, 80 color 35 mm slides, and a cassette tape with narration and music. It can serve as an educational medium for public schools, or an enjoyable resource program for youth organizations, conservation clubs, etc.

The Nevada Chapter produced the program. The Chapter is composed of professional wildlife biologists and managers representing various Federal and State wildlife agencies, universities, and private organizations.

Orders should be sent to the Nevada Chapter of The Wildlife Society, University of Nevada, Department of Range, Wildlife and Forestry, 1000 Valley Road, Reno, Nevada 89512. The cost of the program is $65.00 plus $4.50 for mailing. Include your name, address, and check or money order. ●

FILE SNAKE SURVEY

The Reptile Department at the Royal Melbourne Zoo is conducting a survey on husbandry and propagation techniques for Arafuran file snakes *(Acrochordus arafurae)*. They request the following information from institutions or individuals which currently maintain (or have previously maintained) this species or other fully aquatic species of snake:

- Species maintained and duration in the collection
- Disease or husbandry problems encountered
- Techniques for treating problem(s) mentioned above, and success rate
- Comments and suggestions

MOSSY-BACKED TURTLES SOUGHT

Dr. L. C. Colt, Jr., of the Biology Department of Southeastern Massachusetts University, is seeking samples of the green alga *Basicladia*. This alga grows as a mossy-green coating primarily on the backs of turtles.

If any reader has turtles with this type of coating on the carapace, or knows of institutions with such turtles in captivity, or might be in a position to collect such turtles, please contact Dr. Colt at:

Biology Department
Southeastern Massachusetts University
North Dartmouth, Massachusetts 02747
U.S.A.
(617) 999-8230 or (617) 359-6013

Sample bottles, preservative, and collecting instructions will be sent to any investigator who can provide the samples. Wild-type samples are sought primarily, but any samples will be useful. ●

HL NOTICE

It has been brought to our attention that the reprinted copies of *Herpetologica* Volume 10(2) are incomplete (pp. 103-106 are missing). If your copy is missing these pages please write to the Publications Secretary for an insert.

CORDYLID PUBLICATION

The Museum National d'Historie Naturelle has recently published "Les Gerrhosaurinae de Madagascar" by E. -R. Brygoo, as Memoires du Museum, Ser. A Zool., Volume 134. This is a revision of the two genera of Madagascan cordylids, *Tracheoloptychus* and *Zonosaurus*. For each species, the taxonomic status and diagnostic characters are examined. A key to the species of *Zonosaurus* is provided, as well as distribution maps and numerous line drawings. Price is 108F (+ 4% for shipping and handling). This Memoir and others are available from:

Service de Vente des Publications

75005 Paris ●

NYZS TORTUGUERO TURTLE-TAGGING PROGRAM

Volunteer field assistants cataloged 2,427 green and 10 hawksbill turtles during the 1985 season. Sponsored by the New York Zoological Society and the Caribbean Conservation Corporation, 19 men and 19 women recruits, assembled into 5 teams, patrolled a five-mile section of beach each night from 13 July through 21 September. Program participants thoroughly monitored the activities of all turtles that emerged from the sea and tagged all unmarked individuals before they returned to the Caribbean.

In 1986, NYZS-CCC will repeat the turtle-tagging mission to Tortuguero. The project, now in its third year, is designed to support and augment the green turtle research that has been directed by Professor Archie Carr of the University of Florida for the past 30 years. The New York Zoological Society is now gearing up for the 1986 season. Five teams of dedicated people will be assembled to patrol the Tortuguero beach during July-September 1986. Additional information and applications are available from John Behler, Curator, Department of Herpetology, Bronx Zoo, Bronx, New York, 10460, U.S.A. ●

KANSAS HAS STATE REPTILE

The governor of Kansas has recently signed a bill which designates the ornate box turtle *(Terrapene ornata ornata)* as the state reptile of Kansas. Through the efforts of Mr. Larry Miller and his sixth grade class at Caldwell Elementary School in Caldwell, Kansas, a well-researched proposal was provided to wildlife, environmental and educational organizations, to colleges and universities, to the media, and to the lawmakers in Topeka.

SOCIETIES

OKLAHOMA HERPETOLOGICAL SOCIETY

Founded April 1976, the Oklahoma Herpetological Society's purpose is threefold:

1) To encourage education and dissemination of scientific information through the facilities of the society;

2) To encourage conservation of wildlife in general and of amphibians and reptiles in Oklahoma in particular;

3) To achieve closer cooperation and understanding between amateur and professional herpetologists, so that they may work together in the common cause of furthering science.

Membership numbers 75 and is open to all. Members receive the society's newsletter, bulletin and special publications.

Dues for the calendar year 1986 are as follows:

Regular member	$7.00
Family member	$9.00
Contributing member	$15.00

Make checks and money orders payable to OHS. Send subscription requests to:

Linda C. Putnam
Rt. 8, Box 580
Claremore, Oklahoma 74017, U.S.A. ●

WISCONSIN HERP SOCIETY PLANS SYMPOSIUM

The Wisconsin Herpetological Society is planning a 1986 Midwest Regional Herpetological Symposium on October 17, 18 and 19. The meeting will be held at the Milwaukee County Zoo's Aquarium Reptile Building. Individuals wishing to present papers should submit titles as soon as possible. For further information contact:

THE GREATER CINCINNATI HERPETOLOGICAL SOCIETY

The Greater Cincinnati Herpetological Society, founded in 1977, provides a vehicle for information and resources exchange between its members. Through education, responsible research, and example the society zealously promotes the welfare of reptiles and amphibians.

The GCHS provides information to its members regarding herpetologically related legislation and threatened and/or endangered species. Society members are available to community groups or educational facilities for lectures. Members are active in "white bag runs" on a year round basis, rescuing reptiles from the homes and yards of frightened or concerned citizens. These animals are released into more appropriate locations. The society sponsors periodic trips to observe the animals in the field and also behind the scenes at various zoos.

The highlight of the year is the annual GCHS sponsored "Herp Show" at the Cincinnati Museum of Natural History. Live animal displays, demonstrations and lectures draw large crowds to the museum for this exciting event.

The GCHS newsletter, published monthly and distributed to 125 members, has grown from a one page "flyer" to a professional 10-12 page bulletin which includes an illustrated cover, pertinent articles, news items, a question and answer column and classified ads. Articles and papers submitted for publication are welcome.

Membership is open to anyone with an interest in herpetology. Dues for 1986 are:

Family	$15.00
Individual	10.00
Student	8.00
Corresponding	8.00

NORTHERN NEVADA HERPETOLOGICAL SOCIETY

The Northern Nevada Herpetological Society was formed in 1984 to educate its members and the public in the field of herpetology and wildlife conservation. The society has a membership of about 50 in the United States and Canada. Membership is open to anyone interested in the field of herpetology. Monthly meetings are held in Reno, Nevada the second Wednesday of every month, featuring films, guest speakers, and educational discussions. Membership includes a subscription to the society newsletter, published every other month. The price for membership is:

Regular Member	$7.00
Family Membership	$25.00
Contributing Member	$25.00

Please make checks and money orders payable in US funds to NNHS, and please include your address.

MEETINGS

FALL ESHL MEETING

The Eastern Seaboard Herpetological League (ESHL) will hold its Fall meeting on Saturday, 18 October 1986 at the Peabody Museum, Yale University, New Haven, Connecticut. Presentations will be given on the following topics: Recognition and Prevention of Diseases in Reptiles, the Chemistry of Venoms, Defense Mechanisms of Amphibians and Reptiles, and Pathology of Reptiles. There will also be a workshop on Keeping Regional Herpetological Societies Healthy. A tour of the Peabody Museum may be scheduled. All individuals interested in herpetology are invited to attend. There is no admission fee. The meeting is being hosted by the Connecticut Herpetological Society. For further information contact:

Michael J. Urichek
77 Faber Avenue
Waterbury, Connecticut 06704, U.S.A. ●

SOCIETAS EUROPAEA HERPETOLOGICA

The Faculty of Natural Sciences, Catholic University, Nijmegen, will host the 4th Ordinary General Meeting of the SEH, 17-21 August 1987. The program will consist of oral and poster presentations, social gatherings, and a one-day field trip. Workshops will focus on "The Use of Telemetry in Herpetological Studies" and "Vocalization in Anura." All contributions will be presented in English.

A detailed program and call for papers will be delivered during or after September 1986 only to those who request them. For further information write to:

Dr. Jan J. van Gelder
Catholic University Nijmegen

FEATURES

IDENTIFICATION CHARACTERISTICS OF ANURAN TADPOLES

Because of the small number of diagnostic traits that can be evaluated easily, subjective evaluations are commonly used in the identification of tadpoles. We point out additional traits or character states that might be considered in the identification of tadpoles. Characters do not have to be taxonomically universal to be of great help.

CHARACTERS

Color Patterns. Shapes and distributions of chromatophores can be distinctive, such as the chain-like patterns of melanophores in *Discoglossus* and *Pelodytes* (Boulenger 1891) and the abrupt switch from punctate to stellate melanophores in the tails of *Hyla gratiosa* tadpoles (Altig 1972). Some stream hylids and leptodactylids from Central and South America have bundles of parallel rodular melanophores arranged at right angles to each other. Pigmentation of the vent tube, spiracle tube, eyes, nostrils, pharyngeal walls, peritoneum, limb buds, and viscera often offer distinctive features but have never been systematically examined and are seldom used.

Nostril. More attention needs to be given to the aperture shape and size and detailed configurations of the opening (level with surface, countersunk, partial or complete surrounding rim, and presence, number, shape and distribution of papillae (see Inger 1983).

Spiracle. A primary concern involves those species that have the spiracle located well below the horizontal longitudinal axis so that neither sinistral (= laevogyrinid) nor mediogyrinid are entirely applicable. We suggest paragyrinid (e.g., phyllomedusine hylids, pelobatids) to describe a spiracle that lies between a point next to the midline and about 70 degrees counterclockwise as one imagines the animal in cross-section at the level of the spiracle. This term avoids excessive qualification of the term sinistral. Secondly, detailed configurations of the spiracle tube (medial wall absent or present as a partial or complete ridge versus a free medial wall) offers more information than is commonly presented.

Vent Tube. Cei (1980) noted a case in *Pleurodema* where the vent was "almost sinistral." If this is not a preservation artifact or a case of reversed symmetry (one *Mixophyes balbus*, UMMZ 154850, has reversed symmetry), it represents a new category.

The categories medial and sinistral should be evaluated solely on whether feces emerge in line with (medial) or anywhere to the right of the vertical plane of the ventral fin (dextral), regardless of the orientation of the tube proper or kind of association with the fin. There are several ways of being dextral: a circular tube (ignoring collapse) with walls attached at the same site to the fin; the same attached at the same site to a web between vent tube and fin; right wall displaced dorsally, anteriorly, or both (aperture no longer circular); or the attachment of both walls displaced to the right with or without a web. Several other types of dextral vents are not associated with the ventral fin or tail muscle (e.g., *Phyllomedusa guttata*, some myobatrachids). Medial vent tubes may have no association with the ventral fin, be within the ventral fin, or may be attached dorsally to the fin for part or all of their length with or without a web. The ventral wall may be shorter than (aperture a slit), equal to (aperture circular), or longer than the lateral walls. Contrast in these and other translucent features can be increased by histological stains or lyophilization (Altig 1974).

Jaw Sheaths and Labial Teeth. The buccal face of the upper jaw sheath (Altig 1973) may be diagnostic because of differential sloughing of cells. Shapes of cross-sections of jaw sheaths may be diagnostic or at least have ecological significance. The shape of the basal margin of keratinization on the buccal face of the sheath is often distinctive. Serration density (number/mm), depth, shape and orientation should be noted in more detail. The density of labial teeth seems to be stable

once the oral features are entirely formed, and more data are needed on the occurrence, number and configuration of cusps.

Lateral-line Pores. Patterns of lateral line pores (Boulenger 1891) are seldom used diagnostically because they are difficult to see; Lannoo (1985) solved this problem and indicated the presence of taxonomic traits. Many stream tadpoles in several families have the last posterolateral pore on the body greatly enlarged.

Buccal Papillae. Wassersug (1976, 1980), Inger (1985) and others have used these structures in the context of systematics and ecology. Configurations of these papillae aid identification in some cases.

EXPERIMENTS WITH GOPHER TORTOISE *(Gopherus polyphemus)* RELOCATION IN SOUTHERN MISSISSIPPI

Gopher tortoise *(Gopherus polyphemus)* populations in Louisiana and Mississippi have declined drastically since the arrival of European man and Louisiana populations are probably functionally extinct (Lohoefener and Lohmeier 1983). Throughout the gopher tortoise's range in the southeastern United States the conversion of pine (*Pinus* sp.) from natural open stands to planted dense stands has reduced gopher tortoise populations (Auffenberg and Franz 1982). The gopher tortoise is a colonial species and Lohoefener and Lohmeier (1981) believed that many pine forest management practices caused fragmentation of tortoise colonies. Lohoefener (1982) believed such fragmentation decreased the tortoises' reproductive potential and increased human predation. In Mississippi the gopher tortoise population consists mostly of isolated tortoises and there are many areas of suitable soils and topography from which gopher tortoises have presumably been extirpated. Any long-term gopher tortoise recovery plan in Mississippi will probably have to include relocation of isolated tortoises to re-establish colonies.

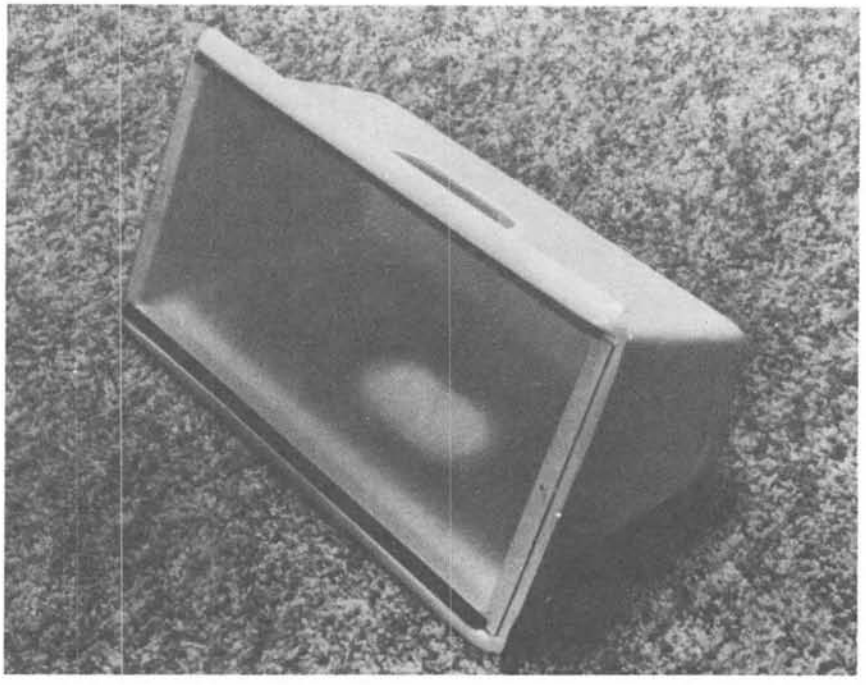
Little information is available on gopher tortoise relocation. This paper reports our attempts to relocate gopher tortoises in southern Mississippi.

METHODS

Relocation efforts were conducted during the spring and early summers of 1980, 1981, and 1982. Forty mature or nearly mature tortoises were used. Five tortoises were acquired from the Louisiana Nature Center. Four tortoises (probably released captives) were found wandering in a floodplain devoid of gopher tortoise habitat. Six tortoises (probably wandering feral tortoises) were found on southern Mississippi roads in areas lacking resident tortoises. Eleven tortoises were trapped at their burrows in southern Mississippi road ditches. Nine isolated tortoises were trapped at their burrows in forest habitats and five tortoises were trapped in areas that had recently been clear-cut.

Only five of the tortoises were less than 23 cm carapace length (CL). Sex determination was not inclusive for all tortoises. All relocated tortoises were marked by drilling one or more 0.32 cm diameter hole(s) in a marginal scute(s).

Five relocation sites were used: an area with seven mature tortoises resident in an open canopy stand of young slash pine *(P. elliotti)* on Eustis soils of 8-17% slope; an area with four mature tortoises resident in a semi-closed canopy stand of 20-30 year old slash pine on Poarch soils of 2-5% slope; an area known to have four mature tortoises resident in an open canopy stand of mature longleaf pine *(P. palustris)* on Poarch soils of 5-12% slope; and two areas of open canopy stands of 15-20 year old slash pine on Eustis soils of 8-17% slope where no tortoises occurred.



In 11 of the 30 trials (11/40 of the tortoises) the relocated tortoises were simply released at the relocation site (Table 1). In 5/30 (5/40 of the tortoises) the relocated tortoises were placed in existing tortoise burrows judged to be of the right size and not currently in use by a resident tortoise. In 3/30 of the trials (3/40 of the tortoises) the relocated tortoises were placed in "started" burrows. The remainder (11/30 of trials, 21/40 of tortoises) were placed in started burrows in pens.

Table 1. Results of experiments with relocation of gopher tortoises *(Gopherus polyphemus)* in southern Mississippi.

Release Method	No. of Trials	No. of Tortoises	Percent Success
Individual tortoises:			
In an area with feral tortoises.	11	11	0
In a started burrow in an area with feral tortoises.	3	3	0
In an abandoned burrow in an area with feral tortoises.	5	5	20
In a started burrow and penned in an area with feral tortoises.	5	5	80
Grouped Tortoises:			
Groups of 3, 3, 3, and 2 placed in started burrows and pens in an area with feral tortoises.	4	11	73
Groups of 3 and 2 placed in started burrows and pens in areas without feral tortoises.	2	5	100

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

NEODESHA PLASTICS INC

TWIN RIVERS INDUSTRIAL PARK
P O BOX 371 – NEODESHA, KS 66757
A/C 316 325-3096

A "started" burrow consisted of a hole being dug with post-hole diggers to a depth of about 1 m and at an angle of about 45 degrees to the ground's surface. An attempt was made to ensure that the width and height of the hole exceeded the tortoise's carapace length and height. A shovel was used to shape the hole into the typical "half-circle" shape of a real tortoise burrow. All soil excavated was mounded and packed in front of the started burrow.

Of the penned tortoises, 5/11 of the trials used individual tortoises and the other six trials used groups of two or three tortoises (Table 1). The pen was constructed using 61 cm wide pieces of heavy translucent vinyl sheeting of varying lengths. The sheeting was arranged in the form of a circle and held erect by stapling to wooden stakes. About 10 cm of the sheeting's width was buried. When only single tortoises were enclosed the diameter of the circle was about 4 m, otherwise the diameter was about 7 m. Usually the pens were left erect for two to four weeks. However, in 4/11 of the trials, including both "new area" releases, the pens were knocked down by animals before two weeks had elapsed.

Where feral tortoises already existed a successful relocation was judged to have occurred when a new burrow became active in the area and subsequent trapping caught the marked tortoise. A relocation was judged as unsuccessful if no new burrows occurred in the study area and the marked tortoise was never again captured. In the two areas where no feral tortoises existed, success was judged by presence of new tortoise burrows. Because of human predation in the study areas no study period was longer than one season and successful relocation is based on whether the relocated tortoise was still present in late summer or early fall.

RESULTS

Only one relocation was successful among the 19 unpenned tortoises placed in areas where feral tortoises occurred (Table 1). All 21 tortoises placed in pens were also placed in started burrows and seventeen (81%) of these relocation attempts were successful.

Following the initial placement, many tortoises were never again observed to be in the started burrow. Following release in the pen, only 6/21 of the tortoises were observed to have excavated the started burrow. Once the pens were removed none of the relocated tortoises stayed in the artificial burrows. Of the tortoises that remained in the study area, all excavated burrows elsewhere.

Of the 18 unpenned tortoises that left the study area, three are known to have returned to near the place of capture. These three tortoises had been removed from clearcut areas and relocated to areas about 1.5 km distant. One tortoise returned to within 3 m of its original burrow. The other two dug new burrows within 100 m of their old burrows.

DISCUSSION

MacFarland et al. (1974) reported the results of releasing 71 captive raised, five year old Galapagos tortoises *(Geochelone elephantopus)* in an area of feral tortoises. They reported the behaviors of the released tortoises and young feral Galapagos tortoises were similar. Ten months after release the overall dispersal of the toroises was not great and the survival and health of the released tortoises was encouraging.

Berry (unpublished 1972-75 contract reports, see Hohman et al. [1980] for an annotated listing) experimented with relocation of desert tortoises *(Scaptochelys agassizii)*. She relocated desert tortoises to areas where feral desert tortoises already existed. The tortoises were not penned nor provided refugia. Berry believed her efforts to be generally successful, with relocated feral tortoises probably having a greater chance of survival than relocated captive tortoises.

Cook et al. (1978) and Weber et al. (1979) reported on the reloction of former "pet" desert tortoises to areas lacking feral tortoises. All tortoises were held for a period of time (to ensure they were not diseased) and then released. No pens or refugia were provided. Based on the number of tortoises found dead after one year the survival rate was estimated to exceed 70 percent.

Our study would have been improved by penning some tortoises without started holes and penning where abandoned real burrows were present. However, we were concerned with feral dog predation and felt obligated to provide refugia.

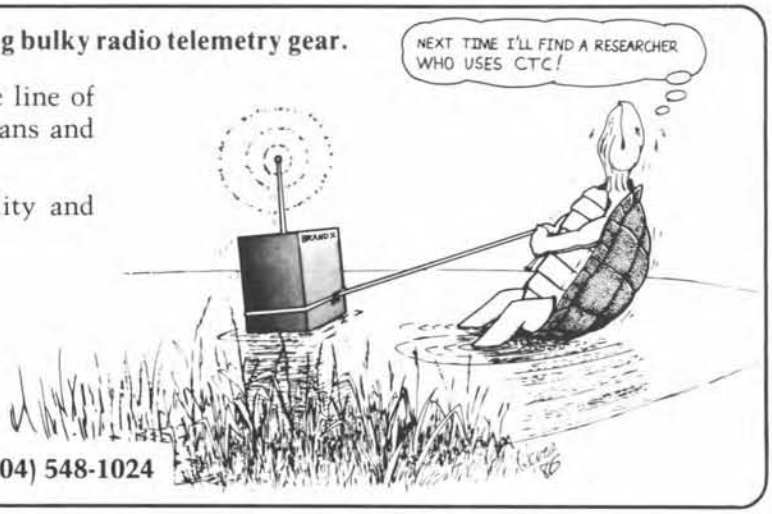
All five tortoises we relocated to areas lacking feral tortoises were captive tortoises from New Orleans, Louisiana. We were concerned with possible disease transmissions and these tortoises were placed on small "islands" of upland soils that were completely surrounded by creeks or extensive wet areas. The high rate of success (100%) for these tortoises may have been attributable to this isolation.

Our results indicate that simple release of relocated tortoises in areas where feral tortoises occur may not be worthwhile. Except for perhaps providing shelter, the artificial starting of burrows, at least by our methods, did not seem to enhance the success rate of tortoise relocation. Our results indicate that the penning of the tortoises in the release area increases the relocation success.

However, our results are at odds with those of other gopher tortoise relocation studies. Landers (unpubl. ms., see Diemer [1984]) placed 79 adult tortoises among four sites, each about 5 ha in size, on which low numbers of feral tortoises were already present. None of the relocated tortoises was penned but some were placed in existing burrows and others placed in started burrows. Overall, Landers reported that about 40% of the tortoises remained in the area of release.

Contrary to our results, Landers found nine of the 12 tortoises that were placed in started burrows converted these starts into burrows and became resident. Landers reported that on at least five occasions the relocated tortoises initially left the release site but returned during "the next few months."

N. Mills (pers. comm.) has relocated four tortoises from Louisiana to Mississippi. In each instance the relocated tortoise was placed in an existing colony of feral tortoises but not in a pen. He believes his success rate has been 100%.



Diemer (1984) recently addressed the ethical and ecological problems associated with tortoise relocation in Florida and presented preliminary results for one relocation project. In 1978 twenty-nine (24 marked) gopher tortoises were penned and later released in an area where feral tortoises occurred. In 1983 seven of 12 tortoises recaptured were of the original 24 marked.

No species of study should be burdened with carrying bulky radio telemetry gear.

Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

Custom design, high quality components, reliability and reasonable prices...that's *CTC*.

Please inquire for more detailed information.

CONCLUSIONS

There is a great need for comprehensive and well-planned gopher tortoise relocation studies. If the gopher tortoise is to remain part of Mississippi's naturally occurring fauna a relocation of isolated tortoises to areas where colonies can be protected will be necessary. To save the gopher tortoise from extinction in Louisiana such work would have to be done immediately.

In Mississippi, where suitable gopher tortoise habitat is usually found as small widely separated upland areas, preliminary recommendations might include the following. Only isolated feral tortoises should be used in relocations. If at all possible the relocation site should have supported tortoises in the past. When possible the sex ratio of relocated tortoises should be approximately 1:1. Based solely on our results, relocated tortoises should be penned at the release site for at least one week. Some measures should be taken to ensure that the penned tortoises are protected from human and animal predation.

Relocating gopher tortoises is very labor intensive and time consuming, thus expensive. The results can be obliterated by one human predator. It is highly desirable that the other southeastern states with gopher tortoise populations do not allow the populations to decline to the point where survival of the species in the wild is dependent upon relocation efforts.

We thank R. Thomas and the Louisiana Nature Center for tortoises. We thank the editor and reviewers for assistance with the manuscript.

ARCHAEOLOGICAL EVIDENCE OF *Emydoidea blandingii* IN MAINE

In 1966, 651 bone fragments were recovered from an Indian site on Hog Island, Lincoln County, Muscongus Bay, Maine. The site is an Indian shell midden composed mostly of soft-shell clams, *Mya arenaria.* An examination of ceramic sherd fragments and two stone projectile points leads to an estimated period of occupation between 500 BC and 1500 AD. Among the bones collected were fragments of two turtles: a 9th right marginal, probably from a painted turtle, *Chrysemys picta,* and 10 fragments representing a single section of an adult Blanding's turtle shell. The Blanding's turtle fragments consist of nearly complete 2nd, 3rd, and 4th neural bones and the attached proximal ends of the left 2nd and 3rd pleural bones. The 3rd neural measures 35 X 23 mm, suggesting a specimen of approximately 225 mm total carapace length. These shell fragments are stored at the Department of Archaeology, University of Maine, Orono as site number 17.22 in the Maine Archaeological Survey System. This Blanding's turtle specimen represents the first record of the species from an archaeological site in New England and is evidence that the species was indigenous to New England in pre-colonial times.

Recent Blanding's turtle specimens found in Maine include those reported by Packard (1960) and Graham and Doyle (1973). A specimen reported from Hampden Highlands (Barden 1952) was a misidentified wood turtle, *Clemmys insculpta,* (McCoy 1973; Graham and Doyle 1973) and an animal found in the 1950s on Mt. Desert Island (Coman 1981) was most likely an escape. McCoy (1973) summarized the range of the species.

Appreciation is extended to Peter Meylan of the Florida State Museum, University of Florida, for verifying the identification of the shell fragments. Art Spiess of the Maine Historic Preservation Commission and Russell Barber, former director of the Institute of Conservation Archaeology, Peabody Museum of Archaeology, Harvard University, examined cultural artifacts from the site and estimated the period of occupation. Appreciation is also extended to Duryea Morton and Stephen Kress, past and present directors of the National Audubon Society's Ecology Workshop on Hog Island, for permission to examine the material and publish this report.

PSEUDOCOPULATION IN *Eumeces laticeps*

The first observation of pseudocopulation in female lizards under natural conditions was made on a parthenogenetic geckonid, *Lepidodactylus lugubris* (Werner 1980). Male-like courting and mounting has been observed under laboratory conditions in both unisexual and bisexual *Cnemidophorus,* Teiidae, in a scincid, *Eumeces egregius* and occasionally in an iguanid, *Anolis carolinensis* (Cole and Townsend 1983; Crews and Fitzgerald 1980; Cuellar 1981; Mount 1963). Here I report on an instance of pseudocopulation during a staged encounter under natural conditions between two female scincids, *Eumeces laticeps.*

On 8 June 1984 at a study site in Scott Co., Illinois I presented a tethered female *laticeps* (107 mm SVL, collected on 4 June 1984) at the end of a bamboo fishing pole to a resident female *laticeps* (115 mm SVL). This is a technique that has been used at the study site to study male-male interactions. Portions of the pseudocopulation were filmed with a Beaulieu Super 8 movie camera. Film analyses were made with a Lafayette Super 8 film analyzer. Gender identification in this species was determined by the obvious sexual dimorphism during the breeding season.

The resident female was observed at 1105 h. She lay on the ground with her head and body in the sun while her pelvic region and tail were hidden under the floor of a small building. Upon presentation of the tethered female at 1107 h the resident ran back under the building. At 1109 h the resident, assumed to be the same female, reemerged, approached the tethered female and tongue-flicked the base of her tail. At 1110 h the two females were lying side by side. At 1111 h the resident moved close and secured a neck bite hold on the tethered female. She then arched

her body over the tethered female and twisted the base of her tail under the tail of the tethered female to appose the cloacae (Fig. 1). Pelvic thrusting by the resident occurred ca. every 2 s. The resident released the neck bite hold at 1116 h and moved under the building. Shortly thereafter she reemerged and was captured.

Figure 1. Pseudocopulation in female *Eumeces laticeps*.

Interpretation of this behavior is difficult. Several variables, e.g., social, spatial, physiological, (or some combination of these) may explain the behavioral sequence. Since the resident was larger than the intruding female, this may have been an expression of social dominance. However, in male *laticeps* dominance is achieved through a ritualized assessment strategy involving biting of the occipital region (Moehn, in prep). Neck bite hold, cloacal apposition and pelvic thrusting have not been observed in numerous male-male interactions.

Spatial relationships may have been important. The resident female had previously been observed in the same area on 4 June 1984 and on 6 June 1984. Her home range was located ca. 75 m from three different foci of male activity. No males had been observed in her home range prior to 8 June during 1984. Her relative spatial isolation may have produced "ersatz," i.e., mating with one's own sex in the absence of the appropiate sex.

A more satisfying explanation is a physiological one. Because neither female was dissected, their ovarian conditions are unknown. However, reproduction in the Scott Co. population was delayed in 1984 because of the cool spring. Reproductive activities normally peak before the end of May. In 1984 the first instance of female tending by a male was observed on 4 June. The resident may have been preovulatory on 8 June and perhaps her preovulatory state produced the pseudocopulatory response. In parthenogenetic *Cnemidophorus* male-like behavior is more often associated with the postovulatory condition (Crews and Fitzgerald 1980), but I simply suggest that the resident female's ovarian/hormonal state, whatever it may have been, provides the most heuristic explanation for this behavior. Regardless of the social, spatial or physiological factors involved, the observation does suggest that pseudocopulation between females may occasionally occur under field conditions in sexually reproducing lizards.

In captivity the resident female copulated with a male on 14 June 1984 and on 22 June 1984 she deposited a clutch of 11 eggs. Both females had been toe-clipped and they were returned to their respective capture sites on 16 July 1984.

I thank Illinois College for financial support.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

COURTSHIP AND REPRODUCTION IN CAPTIVE CRETAN VIPERS, *Vipera lebetina schweizeri*

The Cretan viper, *Vipera lebetina schweizeri* is an oviparous, dwarf form (to 80 cm) of the leventine viper occurring on islands in the West Cyclades, Greece. The Greek Department of Agriculture presently offers a bounty of 10 Drachme per snake which results in an annual harvest of about 600-1000 vipers by inhabitants of Milos. In addition several hundred are taken annually by collectors (Honegger 1977). Honegger (1977) considers the subspecies to be endangered with a total population estimated at 3000-5000 specimens. Currently in need of protection, the future survival of the Cretan viper may depend upon captive management programs.

Information regarding the Cretan viper's reproductive biology in captivity is scanty. Schweizer (1957) reported on the artificial incubation and hatching of eggs laid by a wild-caught female. Stemmler (1967) observed combat between males as did Schweiger (1981), who further recorded copulation. The most inclusive account of the snake's reproductive biology in captivity is by Westrin (1983), who reported combat between males, copulation, egg laying, incubation and hatching.

This paper presents information on the successful reproduction of a pair of *Vipera lebetina schweizeri* at the Dallas Zoo for three successive years, 1980-1982.

MATERIALS AND METHODS

An adult sexual pair of *Vipera lebetina schweizeri*, from an unknown locality, arrived at the Dallas Zoo on 28 November 1977. The snakes were initially maintained at a relatively constant year round temperature (26-29° C).

From early March to early December the snakes were housed together on exhibit in a fiberglass enclosure measuring 77.5(l) x 60.2(w) x 38.0(h) cm. Rocks, plastic plants and a water bowl were provided on a sand and gravel substrate. Lighting was provided by two 20 watt Sylvania cool white fluorescent tubes (F20T12/CW). For the 1980 season only, one of the fluorescent tubes was replaced with a blacklight (Sylvania, F20T12/BL). A 50 watt infrared spotlight (Sylvania Corp.) created a basking spot in one corner of the exhibit. The artificial lights provided a photoperiod of 12L:12D. Skylights provided a natural photoperiod for the Dallas, Texas area. Ambient temperature varied from 26-32° C. The snakes were fed 1-3 freshly killed laboratory mice every three weeks.

Every year during hibernation, the snakes were housed in a 15 gallon, screen-topped glass aquarium. A hide box, rocks and a water bowl were provided on a newsprint substrate. Cooling took place in a converted convection freezer with a Honeywell thermostat (type T6021A). Beginning in early December the ambient temperature (26° C) was lowered approximately 2° C daily until 13° C was reached. The temperature remained constant until the last week of February, at which time the temperature was elevated 2° C daily until the ambient temperature reached 26° C. The snakes were not fed during hibernation. The pair was placed back on exhibit during the first week of March. After hibernation the female was provided with a container filled

with moist sphagnum moss for egg deposition.

In 1980-1981, eggs and hatchlings were weighed to the nearest 0.1 gram using an Ohaus triple beam balance. In 1980-1981, eggs were measured to the nearest 1.0 mm using a vernier caliper. Hatchlings were measured using the technique of Quinn and Jones (1974). In all three years the eggs were incubated using the method of Tryon (1975) and kept at an ambient temperature of 27-31° C.

Each hatchling was housed individually in a one gallon jar filled with ca. four inches of pea gravel. A small water dish was sunk into the gravel. A rock, plastic plant and a piece of bark were provided for shelter.

OBSERVATIONS AND DISCUSSION

Courtship was noted for the first time on the morning of 30 March 1980 and continued throughout the next day. The female's tail was elevated to the vent with the posterior half of her tail looping over her body. The cloaca was held agape at the time. Periodically the female would elevate her tail to an even greater angle and then gradually let it back down while simultaneously moving her head from side to side. The combined action would usually elicit rapid tongue flicks and head bobs from the male along the female's dorsum. Tail-search copulatory attempt, as described by Gillingham et al. (1977), was frequently misdirected with the male's caudal region in line with the female's cephalic region. Copulation was never observed.

The female first appeared gravid approximately two to three weeks after courtship. The posterior portion of her body had noticeable swelling with discernable masses. Five eggs and two infertile egg masses were laid on 20 May 1980; the latter were discarded. The clutch consisted of four adherent eggs (total mass = 53.5 g) and one nonadhesive egg (mass = 15.0 g). The mean egg mass (n = 5) was 13.7 g. Measurements were: length 39-48 mm, X = 32.2 mm. All eggs hatched 41-43 days later. Hatchling masses and lengths were: mass 7.0-9.3 g, X 8.26 g; total length 188-192 mm, X = 185.8 mm; tail length 19-27 mm, X = 24.5 mm.

In 1981, courtship was observed on 7 April. Copulation was not observed. Ten eggs were laid on 13 June. One egg proved to be infertile and was discarded. Two of the remaining eggs were infertile and were disposed of four days later. Two of the nine eggs were adherent, the rest nonadhesive. Egg mass for the adherent eggs was 28.9 g, for the nonadhesive eggs 13.8-16.9 g, X = 14.5 g. Egg measurements (n = 9) were: length 37-43 mm, X = 39.6 mm; width 23-27 mm, X = 25.2 mm. Seven snakes hatched 37-39 days after egg deposition. Hatchling masses and lengths (n = 7) were: mass 9.0-9.4 g, X = 9.3 g; total length 195-218 mm, X = 202.2 mm; tail length 27-31 mm, X = 28.7 mm. In 1981, even though the clutch size was larger than in 1980, the snakes hatched earlier and were also larger than the 1980 individuals. In the 1981 brood, the first ecdysis occurred 9-10 days after birth; newborn laboratory mice were accepted 19-20 days after the first ecdysis.

In 1982, the adult pair was observed copulating on 7 April. Eleven eggs were laid on 23 June. Three eggs proved to be infertile and were disposed of 31 days later. The remaining eight eggs hatched 48 days after egg deposition. Egg and hatchling measurements were not recorded.

TECHNIQUES

A WARNING AGAINST THE USE OF PETERSEN DISC TAGS IN TURTLE STUDIES

In all of my field studies of freshwater turtles dating back to 1966 I have marked individuals by a notching method modified after Cagle (1939). While the pros and cons of this technique have been discussed elsewhere (Plummer 1979) an additional failing of the method is that anyone picking up a notched turtle usually overlooks the marks, and even if the notches are noticed the sequence (i.e. unique number) they represent is not recorded.

During the course of my studies on the status of the redbelly turtle, *Pseudemys rubriventris*, in Plymouth County, Massachusetts I recognized a need for a marking system which could be employed in addition to the shell notching scheme; a system which would alert the finder to report the turtle's number, location, and the date of the find to myself or the Massachusetts Division of Fisheries and Wildlife. In particular I was interested in getting data on the overland movements of individuals which were occasionally witnessed by passing motorists, cyclists, or hikers. After learning of the application of printed Petersen disc tags to marking Blanding's turtles, *Emydoidea blandingi*, in the field (Erik Kiviat, personal communication) I ordered a set of 1.5 cm round, serially numbered Petersen disc tags, blank backing tags, and pure nickel fish pins from a west coast supplier in the spring of 1981. I affixed these tags to all redbellies considered big enough to carry them, generally those greater than 15 cm carapace length. The tags were attached via a small hole drilled in the center of one of the rear marginals. A nickel fish pin was first inserted through a blank backing tag and then up through the hole in the shell margin. A numbered printed disc was placed over the top of the pin to form a "sandwich" of two discs with the shell in between them. The protruding nickel pin was cut off ca. 1 cm above the top disc, folded (loop-like) back on itself, and then crimped tightly against the top disc by pliers pressed against the pin head on the underside of the shell. The attachments were always very tight and were in fact checked carefully to be sure that they did not move at all when grasped between my thumb and forefinger. This check was done routinely to insure against premature tag loss. Over a period of approximately two years I applied more than 150 Petersen tags to redbellies without incident. Subsequent recaptures of tagged animals indicated that the tags and their attachment were holding up quite nicely. In the summer of 1983 however, I began to notice that the tag attachment on many animals showed signs of loosening.

Although tag retention has been very high through 1985, the loosening of the conventional pin attachments has proven disastrous. From 9 to 24 September 1983, four adult (3♀, 1♂) redbellies became entangled in the one inch, stretched mesh, knitted nylon New Hampshire fyke nets I had been using since

1979. It seems that during their confinement in the body of this trap these turtles have a habit of backing into the side walls and the loosened Petersen tags catch in the mesh. Entangled animals, unable to surface for air, drown. Since this alarming discovery I have discontinued the use of Petersen tags and have religiously removed them from previous tagged turtles. In addition, although I continue to use fyke nets for turtle capture, in waters still containing tagged turtles the fyke nets must be checked three or four times daily to insure that tagged captives don't suffer a similar fate.

Another disturbing occurrence in 1985 was the discovery that Petersen-tagged turtles can also get fouled in snagged or discarded monofilament fishing line. While I have previously freed birds found entangled in monofilament which was apparently discarded onshore, I never envisioned that abandoned fishing line could pose such an insidious threat to tagged turtles. It could be argued that a safer method of attaching the discs might be found, e.g. adhesives or even the monofilament suggested by Randall (1956). Nonetheless, I strongly urge anyone considering the use of Petersen tags in field studies to carefully weigh the hazard these devices pose if they are attached in conventional fashion.

ACKNOWLEDGMENTS

I would like to thank the Office of Endangered Species of the U.S. Fish and Wildlife Service, the Nongame and Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife, and Wildlife Conservation International of the New York Zoological Society for their support of my research.

A METHOD FOR SAMPLING BLOOD FROM HATCHLING LOGGERHEAD TURTLES

Blood collection from hatchling marine turtles (or turtles of comparable size, 4-5 cm straight carapace length) has been accomplished previously by cardiac puncture (Owens & Ruiz 1980) or decapitation (Dunson & Moll 1980). These two methods are unsatisfactory for studies on small turtles requiring repetitive blood sampling. In the case of cardiac puncture, the sample is likely to be contaminated with pericardial fluid, there may be problems in locating the heart through the plastron, and there is always some degree of trauma to the myocardium, depending on the skill of the operator. The disdvantages of decapitation are obvious.

Blood samples have been collected from the bilateral dorsal cervical sinuses of larger turtles (Kooistra & Evans 1976; Limpus pers. comm.; Owens & Ruiz 1980) although this was found to be too difficult in hatchling green turtles (Owens & Ruiz 1980). However, during a study carried out on hatchling loggerhead turtles *(Caretta caretta),* I found the dorsal cervical sinuses to be a very simple and atraumatic site for repetitive blood collection. Other sites for collection from large turtles include the heart (Stephens & Creekmore 1983) and the scapular vein (Avery & Vitt 1984).

Disposable insulin syringes with integrated needles are ideal for collection of small volumes of blood, ensuring minimum loss of sample in the syringe deadspace. If these are not available, a small syringe with a short, narrow gauge needle is adequate (26G, 0.5"). Hold the turtle in the left hand (if you are right-handed) with the carapace towards you and the plastron resting on the fingers. The turtle is restrained by pressing the thumb on the carapace and holding the head between the index finger and middle finger (or between the third and fourth fingers, using the index finger to steady the needle). The neck should be partially (not fully) extended and lightly flexed ventrally. Entry to the cervical sinus should be perpendicular to the skin and just lateral to the midline (Figure 1). The needle should draw blood at a depth of 0.5-1 cm depending on the size of the animal. It is helpful to apply gentle suction to the syringe during entry if unsure about the depth of the sinus.

Blood samples of up to 0.5 ml were taken from 20 g hatchlings when only a single sample was needed, and 0.2 ml samples could be collected daily for up to a week. More than one hundred hatchling loggerheads were sampled in this way and none showed adverse effects attributable to blood collection.

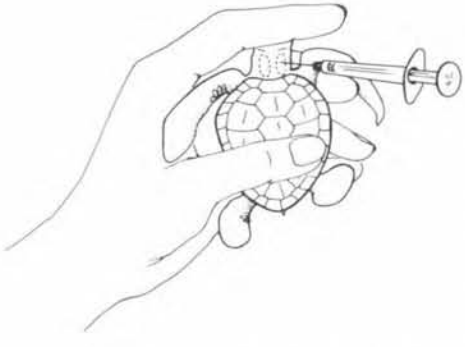

Figure 1. Collection of blood from the dorsal cervical sinus of a hatchling loggerhead turtle. The extent of the sinuses is marked with a dotted line.

ACKNOWLEDGMENTS

This method derives from a study on hatchling loggerhead sea turtles carried out in cooperation with the Queensland Turtle Research Group of the Queensland National Parks and Wildlife Service and the Physiological Ecology laboratory at the University of Sydney.

CANDLING TURTLE EGGS

Turtle and tortoise eggs are slow to hatch. Candling allows an early determination of viability.

Candling is a noninvasive means of looking inside the eggs. It has been done for many years with avian eggs but works with chelonian eggs as well. Although candlers can be bought which are designed specifically for this purpose, an effective substitute can be constructed from items readily available or inexpensively purchased. The procedure takes only a few minutes.

Components needed to construct a candler consist of a large clay flower pot, an extension cord with a bulb socket on the end, a 100-watt light bulb, and a room which can be totally darkened. Fasten the socket to a board in an upright position (Figure 1) and place the flower pot upside down over the bulb. Place the egg to be candled on the drainage hole in the bottom of the pot. Turn on the bulb and darken the room completely. View the egg at right angles to the beam of light coming through the drainage hole (Figure 1) Do not look straight down on the egg from above. If done properly, the entire egg will glow and appear as if it were lit from within.

The eggs of some species afford better views of their contents than others. Many tortoises produce heavy-shelled eggs which are difficult to candle, while smaller turtles tend to produce less calcareous eggs, permitting a better view of their contents. All eggs reveal only a shadowy, blurry, image with no detail,

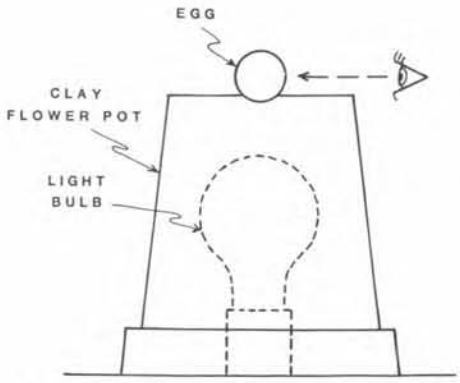

Figure 1. A simple apparatus for candling turtle eggs utilizing a light bulb and a clay flower pot.

requiring some experience for proper interpretation.

A total of 40 eggs of six species were examined by candling after 10 days of incubation at 80° F. At this time, a penny-sized pink membrane could be seen, usually near the top of the egg. Variations in embryo size were observed within clutches as well a interspecifically. The six species observed were *Clemmys guttata, C. insculpta, Cuora flavomarginata, Emydoidea blandingii, Graptemys kohnii,* and *Trionyx ferox*. Arteries, heads, eyes, shells, feet, and yolk became progressively visible with time. The yolk is always on the bottom and glows yellow to orange when candled. Fertile eggs with soft shells usually turn chalky white after a few days, while infertile eggs tend to turn yellow and develop dents.

Figures 2 and 3 are of an egg almost half way through a 60 day incubation period. These figures demonstrate how to interpret the candled image.

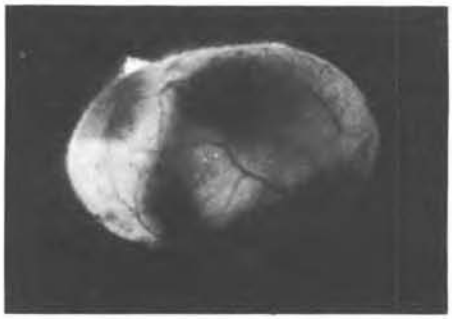

Figure 2. Photograph of a candled *Pelomedusa subrufra subrufra* egg on the 27th day of the 60-day incubation period. Compare with Figure 3. (Photograph by Ted Colvin and Ann B. Bryan).

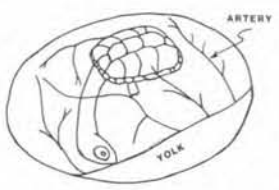

Figure 3. A sketch of the candled egg shown in Figure 2 showing the location and position of the embryo and the location of the yolk and arteries.

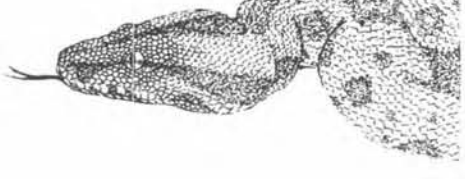
It is not uncommon for hard-shelled eggs to develop permanent air pockets which increase in size during incubation. They can occupy up to one-third of the volume of the egg with no adverse effects on the embryo. Eggs with free-floating air bubbles or cracked shells never hatch. The senior author had one instance of an egg which was punctured from within. It oozed a drop of blood, which was wiped off, and the puncture was sealed with Elmer's® glue. The turtle hatched a month later.

Late in the incubation period the shell, four legs, and head are evident. The head end contains the smallest and fewest blood vessels.



Since turtle eggs develop best when the embryo is at the top of the egg, candling allows one to determine when eggs are not properly oriented and rotate them if necessary. There is currently disagreement on whether or not rotation during incubation is harmful to turtle eggs. Except for this initial reorientation of the egg, the authors do not recommend rotation. Candling also minimizes a disorder that the senior author has termed "full term egg death." This is a condition in which individuals attain full hatching size but fail to hatch. We believe the cause of full term egg death to be related to the membrane enclosing the turtle within the egg. This membrane, through which the turtle respires while in the egg, is withdrawn into the turtle's abdomen at hatching time. If the turtle cannot break out soon after this happens, it will drown. If eggs are opened slightly just before hatching, they will usually survive.

To open an egg, one must candle it daily during the last week of incubation. When an area clear of blood vessels appears at the head end, mark it with a pencil. Then, using a sterilized pin, carefully make a small puncture and wipe away as much liquid as possible, leaving an air pocket in which the turtle may breathe. Return the egg to the incubator and it should hatch by itself.

The following species were hatched in 1985 using the above technique: 50 *Clemmys insculpta,* 8 *C. guttata,* 12 *C. muhlenbergii,* 20 *Terrapene carolina,* 12 *Cuora amboinensis,* 6 *C. flavomarginata,* 2 *Chrysemys picta,* 3 *Cyclemys dentata,* 5 *Chelodina longicollis,* 3 *Graptemys kohnii,* and 18 *Pseudemys scripta elegans.* Three of the *P. s. elegans* had no legs and would not have been able to hatch on their own. They were euthanized two weeks after hatching.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, U.S.A.

ANURA

HYLA REGILLA (Pacific Treefrog). **PREDATION.** An adult Male *Hyla regilla* (2.4 g, 33 mm snout-urostyle length) was observed struggling in the jaws of an adult male red-leg frog *Rana aurora* (45 g, 80 mm SUL). The incident occurred at Blumpond, a stock pond (15 m in diameter, less than 1 m deep) in oak woodland, immediately adjacent to the NW border of Hastings Natural History Reservation, elev. 518 m, Carmel Valley, Monterey Co., CA on 19 January 1986, 2035 h, during a light rain. The *Rana aurora* rested on a mat of aquatic vegetation in the center of the pond. The *Rana* released the *Hyla* during capture but later ingested him in the collecting bag. Approximately 100 male *Hyla regilla* were chorusing in the pond and several male-female pairs were observed in amplexus. Only the one *Rana aurora* was observed.

Submitted by **STEVAN J. ARNOLD,** Department of Biology, University of Chicago, Chicago, Illinois U.S.A. and **TIM HALLIDAY,** Department of Biology, Open University, Milton Keynes, MK7 6AA, England. ●

RANA CATESBEIANA (Bullfrog). **PREDATION.** Bullfrogs are known to be preyed upon by birds (Chapin 1908. Proc. Staten Is. Assoc. Arts Sci. 2:3-8; Jenni 1969, Ecol. Monogr. 39:245-270; Niethammer and Kaiser 1983.

Colonial Waterbirds 6:148-153). Although infrequent reports exist of terns of the genus *Chlidonias* taking frogs (Craig 1974. Ostrich 45:142) or their life stages (Pandit 1982. Indian J. Ecol. 9:181-190), to our knowledge, the only report of any member of the tern genus *Sterna* taking frogs is that of Peabody (1896. Osprey 1:1-3, 21-23) of Forster's terns *(Sterna forsteri)* from Heron Lake, Minnesota consuming dead frogs that had been trapped by ice and feeding live frogs to their young, none of which were identified. Here, we report predation by Caspian terns *(Sterna caspia)* on postmetamorphic *Rana catesbeiana*.

In the course of a study of a nesting colony of elegant terns *(Sterna elegans)* on dikes separating salt evaporating ponds at the south end of San Diego Bay, California during 1980 and 1981, one of us (FCS) made several observations that indicated predation on bullfrogs by *Sterna caspia*. On 9 June 1980, a dead *Sterna caspia* chick was found with a bullfrog. The frog was in its throat; missing a left hind leg. On 6 May 1981, an adult *Sterna caspia* was observed flying overhead with a subadult *Rana catesbeiana* (ca. 80-90 mm SVL) in its bill. On 20 May 1980, one pair of bullfrog legs severed just above the pelvis was found in a *Sterna caspia* nest.

These observations suggest non-incidental predation by *Sterna caspia* on postmetamorphic *Rana catesbeiana* and indicate that bullfrogs were exploited as food during tern reproduction. It is noteworthy that the *Sterna caspia* population at San Diego was not established until ca. 1940 (Gill and Mewaldt 1983. Auk 100:369-381) and that bullfrogs did not become well-established until about this time (Jennings and Hayes 1985. Herpetologica 41:94-103). *Sterna caspia* is known to be more plastic than other Sterninae in its nesting habits (Gill and Mewaldt op. cit); our observations suggest plasticity in its choice of prey.

RANA SYLVATICA (Wood frog). **REPRODUCTION.** Wood frogs are explosive breeders, and the earliest anuran to breed in Maryland (late February to early March). Females tend to oviposit their eggs in central egg masses. Colonial egg deposition in wood frogs is thought to function as an insulating mechanism against cold temperatures (Seale 1982. Copeia 1982:627-635; Waldman 1982. Behav. Ecol. Sociobio. 10:169-174; Waldman and Ryan 1983. J. Herpetol. 17:70-72). We report that colonial egg deposition may also function to increase survival, by reducing desiccation.

On 13 March 1985, a mass of wood frog eggs (mass D=0.75m) was noted in a shallow, ephemeral pond in Baltimore Co., Maryland. by 19 March the pond had receded significantly, stranding the eggs on moist leaf litter, 4 meters from the water. After a few hours exposure to the air, the outer-most layers of eggs desiccated, forming a thin (apparently protective) covering around the visible surface of the mass. The inner eggs were observed nightly; they appeared hydrated and developed normally (compared to other eggs still in the pond). On 23 March, after four days of exposure, a heavy rain refilled the pond, inundating the stranded egg mass. Many of the eggs continued to develop and eventually hatched. No change in the size of the egg mass was noted during the four days it was exposed.

These observations represent the first published report of woodfrog eggs surviving prolonged exposure to a terrestrial environment. We suggest that this capability represents a significant advantage to a temperate anuran selected to exploit temporary vernal ponds; and it corroborates previous reports ascribing improved fitness to the practice of communal oviposition.

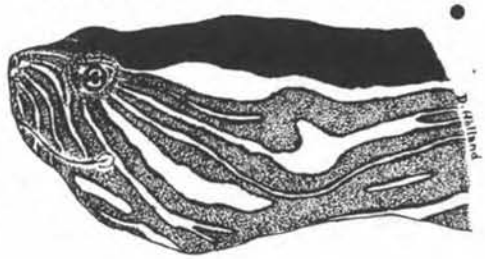
CAUDATA

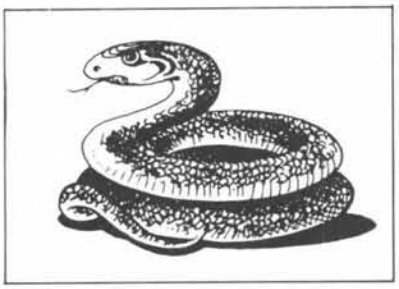
LEUROGNATHUS MARMORATUS (Shovelnose Salamander). **CLIMBING.** Since the species was described (Moore 1899. Proc. Acad. Nat. Sci. Phil. 1899:316-324), no investigator has attributed anything other than a purely aquatic existence to *Leurognathus marmoratus* (Martof 1962. Amer. Midl. Natur. 67:1-35). All of Martof's (1962) several thousand specimens, as well as those collected earlier (Pope and Hairston 1947. Fieldiana-Zool. 31:155-162), were found in trout streams in the southern Appalachians. In addition, the unique morphological features of *L. marmoratus*, such as the fin-like tail, the slit-like choanae, and the rudimentary internasal glands, are considered specializations for an aquatic existence.

During the summer of 1982, I conducted experiments that required the construction of rectangular 5-m^2 pens placed perpendicular to a mountain stream. The long dimension of the pen was arranged so that it spanned 1 m of stream and 2 m of the adjacent streambank and forest floor. I sank 40 cm of 3.2-mm-mesh hardware cloth into and underneath the substrate to prevent salamanders from burrowing into or out of the pens. During construction the substrate was thoroughly searched and all resident salamanders removed. Salamanders from the surrounding area, however, could enter the pens if they successfully climbed the 50-cm sides. Over the course of the summer, 340 salamanders were found, 263 of which were *Desmognathus*. Surprisingly, eight of the salamanders found in two of the four pens were adult *Leurognathus marmoratus*. I am convinced that these salamanders did not enter the pens from beneath the substrate, because no new salamanders were found in the pens when tape was added to the top of the pens to prevent climbing over the sides.

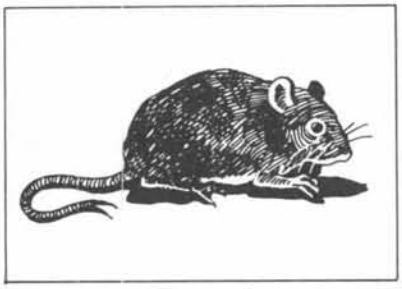
The pens into which the *L. marmoratus* climbed were located on a small second-order stream at elevations of 1200 m and 1220 m on Sugar Mountain, Avery County, North Carolina. I believe this stream to be considerably smaller than those in which *L. marmoratus* is usually found, and had not previously collected *L. marmoratus* here. During the summer months, the stretch of stream between these two pens averages a width of 2 m and a depth of only 6 cm. I have, however, collected *L. marmoratus* from the West Fork of the Linville River at the point (elevation 1185 m) where this small stream flows into it.



Each of the eight *L. marmoratus* discovered in these pens was an adult of undetermined sex, ranging in SVL from 58 to 72 mm ($\bar{X}$ SVL = 65 mm). All eight observations were made during periods of rainy or misty weather between 27 June and 17 September 1982. Two individuals observed at night were climbing above the stream along the top inner edge of the pen. The other six salamanders were found in the stream with none closer than 0.3 m to the streambank. The two nocturnal observations were the only times I have seen *L. marmoratus* outside of a stream pool or riffle. Movement by *L. marmoratus* along the stream current would not have required climbing over the pen sides.



These results are not consistent with the concept of *L. marmoratus* as a completely aquatic salamander. Although this species is generally restricted to areas of moderately deep water, I have presented evidence that individual *L. marmoratus* will leave the stream habitat temporarily. Their ability to traverse vertical walls of fine-mesh hardware cloth reveals a previously unrecognized ability to climb. I believe that short movements out of water and between pools or riffle zones can occur in these salamanders.



Submitted by **MARK T. SOUTHERLAND,** Department of Biology, University of North Carolina at Chapel Hill, North Carolina 27514, U.S.A. ●

PSEUDOBRANCHUS STRIATUS STRIATUS (Broad-striped Dwarf Siren). **MAXIMUM SIZE.** Published accounts suggest that this form reaches a maximum size of 150-152 mm (Martof 1972. Cat. Amer. Amphib. Rept. 118.1-118.4; Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). During 1984-1985 we collected a total of eight adult specimens from Long Co., Georgia, and Jasper Co., South Carolina. Two of these specimens far exceed 152 mm as follows: UF56694, Jasper Co., South Carolina - 175 mm; UF 62657, Long Co., Georgia -203 mm. Specimens are deposited in the Florida State Museum.

SAURIA

CALLISAURUS DRACONOIDES (Zebra-tailed Lizard). **BEHAVIOR.** *Callisaurus draconoides* is typically considered to be a principally insectivorous terrestrial forager, occupying washes and desert pavements where plant growth is scant and there are ample open areas for running (Stebbins, R. C., A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, MA 336 pp.)

On 24 March 1982 I witnessed arboreal foraging by an adult *C. draconoides* in an area of windblown sand and scattered low shrubs a few miles northwest of El Centro, Imperial Co., CA. The specimen observed was situated ca. 5 m above the ground in the branches of a rush-pea *(Hoffmannseggia microphylla)* shrub. It was watched from a distance of 5 m for about 10 min, apparently unaware of my presence. The lizard appeared to be attracted by the activity of flying insects feeding on nectar in the blossoms. It made numerous lunges about in the foliage in the direction of these insects and was, in fact, able to capture successfully this prey at least twice during the time it was watched.

GAMBELIA WISLIZENII (Leopard Lizard). **FOOD.** On 18 April 1982 a female *Gambelia wislizenii* (SVL = 90 mm, TL = 276 mm) was collected in San Bernardino Co., California by Dr. David Morafka. Inspection showed that the individual had ingested an *Uma scorparia* (SVL = 88 mm). *Uma scorparia* has not been a recorded food item although *G. wislizenii* is a known consumer of other lizards (Parker and Pianka 1976. Herpetologica 32(1):95-114). The lizards (ROM 13750) are deposited in the herpetological collections of the Royal Ontario Museum.

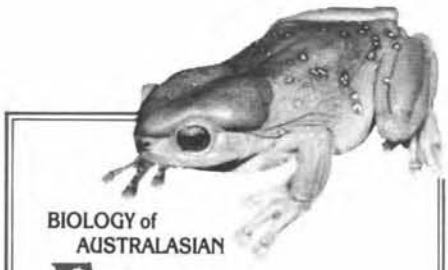
SERPENTES

ALSOPHIS CANTHERIGERUS (Cuban Racer). **DIET.** Predation on hatchling sea turtles by crabs, fish, birds, and mammals is widely acknowledged, but accounts of reptiles as hatchling sea turtle predators are few. Stancyk (1982. Biology and Conservation of Sea Turtles. Bjorndel, K. A. (ed.). Smithsonian Inst. Press, Washington D.C.) in a review of non-human hatchling sea turtle predators, listed two snakes, *Boiga dendrophila* and *Python reticulatus*, as well as varanid lizards in general as hatchling predators. However, Stancyk's (op. cit.) primary source (Hendrickson 1958. Proc. Zool. Soc. London 130: 455-535) noted the records of snake and varanid predation were anecdotal, based on reports from local people.

Brattstrom (1955. Am. Midl. Natur. 54:219-229) presented the only documented data of predation by a snake on neonate sea turtles. During his work on the Revillagigedo Islands south of Baja California, he found a hatchling *Caretta caretta gigas* in the stomach of a *Masticophis anthonyi*. This has been confirmed several times for this snake species (Brattstrom, pers. comm. to Frazier 1985. J. Herpetol. 19(1):1-11). The present report provides an additional record of neonate sea turtle predation by a snake.

On 8 October 1985 at 0920 h, at Cuzco Beach, U.S. Naval Base, Guantanamo Bay, Cuba, I collected an *Alsophis cantherigerus* (SVL 83.0 cm, mass 242.0 g) about 15 m above the high water mark. While in the collection bag, the snake regurgitated a partially digested hatchling sea turtle, later identified as *Eretmochelys imbricata*.

Snakes of the genus *Alsophis* are active foragers and have opportunistic feeding habits (frogs, lizards, snakes, birds and mammals have been recorded) based on unpublished stomach content data, *Alsophis* (*N* = 466, R. W. Henderson, pers. comm.). With regard to these diet data, predation on *Eretmochelys* by *Alsophis* is not unlikely, but probably uncommon. Both the *Alsophis cantherigerus* (UMRC 86-1) and the *Eretmochelys imbricata* (UMRC 86-2) are deposited in the University of Miami herpetology collection.



L. White is thanked for arrangements at Guantanamo and A. Schwartz, N. J. Whitcher, and J. M. Savage are thanked for providing funding. P. Meylan, H. Greene, and J. Frazier are thanked for responding to my inquiries. J. M. Savage and P. N. Lahanas helped positively identify the *Eretmochelys*. M. P. Hayes, and S. D. Werman are thanked for their comments.

Submitted by **BRIAN I. CROTHER,** Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124, U.S.A. ●

ATHERIS CHLOROECHIS (West African Bush Viper). **REPRODUCTION.** Information in the literature regarding reproduction in the West African bush viper is scant. Cansdale (1961. West African Snakes. Longman Group Ltd., London, 74 pp.) reported that one East African female contained 11 embryos; however, no measurements of the female or embryos were given.

In February, 1984, I received a wild-caught, gravid *A. chloroechis* (Female A) that measured ca. 700 mm SVL. The snake was housed in a 41 cm X 35 cm X 21 cm glass enclosure with a hardware cloth top. A heat plate was placed under one end of the enclosure to allow thermoregulation prior to parturition. The snake was never observed using this heat source; instead, she spent most of her time on the branch in the opposite end from the heat plate.

On 12 March 1984, Female A gave birth to six living young, ranging from 131-142 mm SVL/161-172mm TL, $\bar{X}$svl= 137.6 mm, $\bar{X}$tl= 166.8 mm, $\bar{X}$ mass = 3.0 g. In addition to the living young, she also passed nine infertile masses. One neonate, born with no tail and severe body kinks, died several hours after birth. The remaining neonates showed no apparent abnormalities.

BIOLOGY of AUSTRALASIAN

Frogs & Reptiles

Edited by
G. Grigg, R. Shine and H. Ehmann

Reviews and Research on the
ECOLOGY, BEHAVIOUR, PHYSIOLOGY, BIOGEOGRAPHY, CONSERVATION, EVOLUTION and REPRODUCTION
of Australian and New Zealand Reptiles and Frogs

This book is the first major review of the Biology of Australasian Frogs and Reptiles. The Australasian herpetofauna is colourful, diverse and spectacular, and has recently attracted considerable attention from research scientists. The framework is not taxonomic but biological, ranging from reproductive behaviour to evolution, from population biology to captive breeding and husbandry, from zoogeography to the conservation of rare and endangered species.

Available from N. Fagin Books Ill., Wildlife Services Col., Wildlife Publication Flor., Herpetological Book N.Y., K. Neitman Tex., Donald E. Hahn Ariz., Avocet Books N.C. or direct from Publishers.

In March 1985, the Houston Zoological Gardens received a wild-caught female *A. chloroechis* (Female B) that measured ca. 600 mm SVL. The snake was set up in an enclosure similar to that of Female A except that the snake was not provided with a heat plate.

On 4 April 1985, Female B gave birth to nine living young, ranging from 138-155 mm SVL / 170-189 mm TL, $\bar{X}$svl= 146.9mm, $\bar{X}$tl= 179.4 mm, $\bar{X}$ mass = 2.4 g. In addition to the living young she also passed four infertile masses.

All the young from both females shed shortly after birth. Body color after shedding was a light-brown or tan. Within 24 h, however, their body color had changed to a light green. The tail tips of the neonates were sulphur yellow (Fig. 1) much like those of juvenile *Agkistrodon contortrix*.

All the young from both broods were sexed and found to be females.

One week after birth, the young from Female A fed upon small *Acris*. They were fed small *Acris* weekly for one month before their diet was changed to newborn mice. The young from Female B were initially offered and ate newborn mice.

Figure 1. Newborn *Atheris chloroechis*

Submitted by **PAUL FREED,** Department of Herpetology, Houston Zoological Gardens, 1513 Outer Belt Drive, Houston, Texas 77030, U.S.A. ●

CARPHOPHIS AMOENUS AMOENUS (Eastern Worm Snake). **COLORATION.** Perhaps due to the diminutive size and secretive habits of the worm snake *Carphophis amoenus* (Ditmars 1936. The Reptiles of North America. Doubleday, Garden City), individuals that are abnormally colored are almost unknown. Exceptions include an entirely pink specimen from Virginia (Allard 1945. Copeia 1945:42), a xanthic specimen from Maryland (Simmons and Stine 1961. Herpetologica 17:206-208), and an albino specimen from Maryland (Harrison 1968. Bull. Maryland Herp. Soc. 4:88-89). The following account is, to our knowledge, the first documentation of an amelanistic partial albino worm snake from Georgia.

The amelanistic *Carphophis a. amoenus* was found in the metropolitan Atlanta area and brought to the Fernbank Science Center, Atlanta (Dekalb Co.), Georgia. Unfortunately, the particulars of collector, collection locality and ultimate disposition of the specimen are unknown; a photograph in the possession of the junior author remains the only record. Instead of the light brown dorsum and pinkish venter typical of *Carphophis* from this area, the entire snake had a creamy yellowish aspect. The eyes were pink. That the snake was 8-10 inches in length indicates that it was probably at least two years of age (Clark 1970. Univ. Kansas Publ., Mus. Nat. Hist. 19:85-194). It is compelling to suggest that albinism presents less of a handicap to the survival of small, semi-fossorial reptiles like *Carphophis*, since their coloration should be under less selective pressure by visually oriented predators than that of larger, more terrestrial forms.

We thank H. B. Bechtel and H. S. Harris, Jr. for their assistance in the preparation of this note.

Submitted by **DAVID G. COOK,** Department of Herpetology, Zoo Atlanta, 800 Cherokee Ave., SE, Atlanta, Georgia 30315, and **DAVID O. FUNDERBURK,** Fernbank Science Center, Atlanta, Georgia 30307, U.S.A. ●

TESTUDINES

CLEMMYS INSCULPTA (Wood Turtle). **ECTOPARASITISM.** Not all accounts of leech *(Placobdella parasitica)* infestations in wood turtles agree on seasonal abundance of these ectoparasites. Harding and Bloomer (1980. Bull. N.Y. Herp Soc. 15(1):9-26) reported that leeches were present during the entire active season in wood turtles in northern Michigan. However, in New York and New Jersey, Koffler et al. (1978. J. Herpetol. 12(4):571-572) reported that leech infestations were highest on wood turtles in the fall and spring, when tightly-packed masses of young leeches were evident on the soft tissues of several areas of the body. These authors noted a marked decrease in the amount of leeches found on turtles soon after emergence from aquatic hibernation (April) and an increase prior to hibernation in October and November. Hulse and Routman (1982. Herp. Review 13(4):116-117) reported leech infestations in wood turtles in April and October, but did not observe the turtles during the intervening months. No accounts of changes in leech loads over time observed in re-captured individual wood turtles are known.

From 21 April to 30 September 1985, we observed leech infestation in wood turtles sampled from a 200 m linear stretch of the Wisconsin River in Vilas County, Wisconsin. The area within 30 m of the river channel was patrolled on foot or observed from a canoe. All wood turtles found were captured by hand, examined for ectoparasites, and marked by notching their marginal scutes and released. One adult female wood turtle was fitted with a radio transmitter and radiotracked throughout the active season. It was examined for leeches upon each re-location. All of the turtles captured (N=18) were adults ($\bar{X}$ CL=19.6 cm, range=17.1-22.6 cm). Of the total captures (N=29), 37.9% (N=11) were recaptures. All of the turtles were located in at least partial sunlight, generally partially concealed by dead vegetation or grasses, and were dry when captured.

Masses of young leeches (1.0 to 1.5 cm diam.) were found on most of the turtles in April, immediately after emergence from hibernation, but became less prevalent later in the season (Table 1). The masses were located in the inguinal cavity, posterior to the hind legs, on the ventral surface of the neck or in the adjacent axillary cavity. None of these areas could be easily exposed to direct sunlight.

Table 1. Monthly variation in leech infestation on wood turtles from Wisconsin River study site in 1985.

Month	No. of turtles	No. with leeches (%)
April	7	6 (85.7)
May	5	2 (40.0)
June	15	0 (0)
July	1	0 (0)
August	1	0 (0)
September	0	—

A heavily infested specimen was captured on 22 April, but was without leeches when re-captured on 27 May. Another infested individual was found on 5 May but was free of leeches when re-captured on 27 May. A third individual was found carrying masses of small leeches (< 1.0 cm diameter) on 27 May, and re-captured leech-free on 2, 4, and 23 June. The reduction in parasite loads corresponded with the movement of the turtles away from the river for nesting (June) and dispersal into surrounding wooded areas. A female wood turtle (18.1 cm CL), radio-tracked from 5 July to 27 September, was re-located 34 times. No leeches were present when it was captured or on any re-capture, even though it was relocated several times in or near the river channel. Koffler et al. (op. cit.) postulated that increased terrestrial activity in wood turtles in the spring reduced leech infestations through desiccation. Our observations support this idea.

We wish to thank Walter Auffenberg for helpful comments on this manuscript. These observations are part of a study conducted under Endangered and Threatened Species Permit #95, issued by the Wisconsin Department of Natural Resources, Bureau of Endangered Resources. The staff of the Demmer Memorial Library, Three Lakes, Wisconsin, was most helpful in gathering background literature for the study.

PHRYNOPS GEOFFROANUS (Geoffroy's Sideneck). **MATURATION.** Captive reproduction in *Phrynops geoffroanus* was reported by Kardon (Inter. Zoo Yearbook, 1981, 21:71-72), while information concerning reproduction in nature was summarized by Pritchard and Trebbau (Turtles of Venezuela, 1984, SSAR). Three of the hatchlings reported by Kardon were acquired by the Columbus Zoo 14 October 1981. These were hatched at the San Antonio, Texas, Zoo in the period 16 June through 3 July 1979. The largest of these, a female, died from undetermined causes 8 February 1986, and was found upon necropsy to contain 11 shelled eggs. At this time the specimen was ca. 6 years and 7 months of age and had a CL of 25.1 cm. Egg size and shape agree well with data presented by Kardon and Pritchard and Trebbau, being

roughly spherical with the largest axis varying from 29 to 31 mm.

Submitted by **MIKE GOODE,** Columbus Zoo, Columbus, Ohio 43065, U.S.A. ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

ANURA

CENTROLENELLA ALBOMACULATA. HONDURAS: Depto. de Colón: 4 km ESE Tulito. 25 May 1985. M. T. O'Shea and J. Eves. Verified by J. M. Savage. British Museum (Natural History) (BMNH 1985-1231). First record for country. Extends range 500 km Northward. (Frost. (ed). 1985. *Amphibian Species of the World.* Allen Press and Assoc. Syst. Collections. Lawrence, Kansas v + 732 p.).

HELICOPS HAGMANNI (Mapanare de Agua). VENEZUELA: TERRITORIO FEDERAL AMAZONAS: Caño Pavones, 40 km NE Puerto Ayacucho (via El Burro) 5°57'N, 67°22'W). 2 February 1981. E. Armas. Museo de Biologia Universidad Central de Venezuela (MBUCV 7039). Puerto Ayacucho (5°41'N, 67°37'W). 10 January 1981. P. Piñate. Estación Biológica de Rancho Grande (EBRG 1909). Las Queseras, 20 km S Puerto Ayacucho, 135 m. (05°30'N, 67°37'W). 21 September 1967. National Museum of Natural History (USNM 217186). All verified by A. Paolillo O. First records for Venezuela. These specimens differ from others (Rossman. 1975. Herpetologica (4):414-418) in having more dorsal scales (29-23, 30-22, MBUCV 7039 and USNM 217186, respectively; ventral scales (136 MBUCV 7039); and subcaudal pairs (60, 63, USNM 217186 and ERBRG 1909. They also have a maximum of 3 temporal scales and 13 infralabials (USNM 217186 and EBRG 1909). The ventral coloration in alcohol is considerably darker, a generally blackish background with a few cream-colored spots arranged irregularly. I thank J. O'Neill, D. Rossman, C. Myers and R. McDiarmid for letting me examine material. Louisiana State University, American Museum of Natural History and the Smithsonian Institution gave financial support and Zona 10 MARNR (Venezuela) provided facilities for studying two of the specimens.

NEW HERPETOLOGICAL RECORDS FOR CUMBERLAND ISLAND, GEORGIA

Cumberland Island, Georgia, is a relatively new National Seashore with a large area designated as Wilderness. Past agricultural and forestry practices, along with feral animals, greatly modified many habitats on the island and likely reduced some of the herpetofauna. Management as a Wilderness area is resulting in marked ecological changes and modifications in relative abundance of some species. Since the surveys of Hillestad et al. (1975. The ecology of the Cumberland Island National Seashore, Camden County, Georgia. Technical Report Series Number 75-5, Georgia Marine Science Center, Univ. System of Georgia, Skidaway Island, Georgia, 299 pp.), several additional species have been discovered and others listed by them have not been confirmed. This paper is the second in a series to define current status of the Cumberland Island biota.

Hillestad et al. (1975) presented an annotated list of 52 amphibians and reptiles. Some of their records were based on observations without specimens, and comments on the introduction of some species lack documentation. Nevertheless, their work is the best comprehensive herpetological report available for the island. We present additions to the Hillestad et al. (1975) list including some species heretofore unreported for the other Georgia barrier islands. Unconfirmed species from their list are also indicated. All specimens are deposited in the U.S. National Museum of Natural history (USNM) and were verified by G. R. Zug.

AMPHIUMA MEANS (Two-toed Amphiuma). Sweetwater Slough Outlet, S of Lake Whitney. 3 April 1984. C. Robert Shoop and Carol Ruckdeschel. USNM 252432. Additional specimens collected from Lake Whitney, Brickhill Pond, North Fraser Road Pond 1, Duckhouse Sloughs, and beach at Sweetwater Slough Outlet. Known also from Sapelo Island (Martof 1963. Herpetologica 19(1):70-72) and St. Catherines Island (Zweifel and Cole, unpublished).

HYLA CRUCIFER BARTRAMIANA (Southern Spring Peeper). Candler Pond. 11 January 1975. Carol Ruckdeschel. USNM 252433. New record for the Georgia barrier islands.

PSEUDEMYS NELSONI (Florida Redbelly Turtle). Beach near Retta Outlet. 4 May 1979. Carol Ruckdeschel. USNM 252439. An additional specimen collected on the beach the same day (both alive) and several have been observed basking in the Sweetwater Slough system. This is the second locality record for the state (Vitt and Johnson 1980. Herp. Review 11(3):80), and the only record for the Georgia islands.

DEIROCHELYS RETICULARIA RETICULARIA (Eastern Chicken Turtle). Candler Beach Road. 14 March 1984. C. Robert Shoop and Carol Ruckdeschel. USNM 252438. This species is known for several Georgia barrier islands (Johnson et al. 1974). Milanich (1973. Florida Anthropoligist 26(3):105-118) found bones of this species in an Indian midden at Table Point, Cumberland Island, but the source of the specimens could have been from another locality.

CHELONIA MYDAS MYDAS (Atlantic Green Sea Turtle). Beach at Dungeness Road. 2 August 1984. David Casey. USNM 252440. Another specimen found dead on the beach 14 July 1984 is in the Cumberland Island Museum. Green turtles probably forage throughout the Georgia coastal region, and one has nested on Jekyll Island (Litwin 1981. Herp. Review 12(3):81).

DERMOCHELYS CORIACEA CORIACEA (Leatherback). Reported previously by Ruckdeschel, Ellis and Shoop (1982. Herp. Review 13(4):126).

EUMECES EGREGIUS SIMILIS (Northern Mole Skink). The Settlement. 19 January 1982. Carol Ruckdeschel. USNM 252434. First record for the Georgia barrier islands.

STORERIA OCCIPITOMACULATA OBSCURA (Florida Redbelly Snake). Near Greyfield, on Main Road. 20 July 1984. S. Theberge. USNM 252437. New record for the Georgia barrier islands.

DIADOPHIS PUNCTATUS PUNCTATUS (Southern Ringneck Snake). Edge of Ashley Pond. 14 August 1983. C. Robert Shoop and Carol Ruckdeschel. USNM 252435. New record for the Georgia barrier islands.

FARANCIA ABACURA ABACURA (Eastern Mud Snake). Plum Orchard mansion. First half of May, 1975. M. Roberts. USNM 252436. First record for the Georgia Barrier islands.

The following species listed by Hillestad et al. (1975) lack voucher specimens, and their occurrence on Cumberland Island is unsubstantiated:

Bufo guercicus, Oak Toad.
Hyla chrysoscelis (= *versicolor* of Hillestad et al.), Gray Treefrog.
Pseudacris nigrita nigrita, Southern Chorus Frog.
Eumeces fasciatus, Five-lined Skink.
Ophisaurus compressus, Island Glass Lizard.
Pituophis melanoleucus mugistus, Florida Pine Snake. A juvenile *Elaphe obsoleta* from Cumberland Island in the Georgia State University collection (GSU 1004, now UGAMNH 6272) was misidentified as this species (C. W. Seyle, pers. comm.).

RECENT POPULATION CHANGES

RECENT POPULATION CHANGES provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term population trends (in excess of 20 years) and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this subsection: Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62026, U.S.A.

ATLANTIC LOGGERHEAD TURTLE NESTING STATUS IN SOUTHWEST FLORIDA

The status of the loggerhead turtle *(Caretta caretta)* is precarious along many of its nesting beaches in North America. The southernmost nesting population in the continental U.S.A. apparently has been something of an exception. Davis and Whiting (1977) concluded that the Atlantic loggerhead turtles nesting on the beaches of Cape Sable and other nesting sites in southwestern Florida were increasing through the time of their study in the early 1970s. They estimated that nesting effort had doubled from the early 1960s to the early 1970s, despite raccoon *(Procyon lotor)* depredations on 49-87% of the eggs laid. To evaluate whether this increasing trend, unusual among sea turtle rookeries, did indeed characterize the status of this population, the censuses of Davis and Whiting were repeated after a lapse of eight years.

To obtain comparable data, Davis and Whiting's (1977) methods were followed. Aerial censuses of fresh crawls were conducted once per week in May and August and twice per week in June and July, 1980. All nesting beaches were censused 23 times during this period. Twenty-five crawls were

examined on the ground to determine if raccoon predation was still occurring. A "total nesting effort" was calculated by interpolating between census dates, following David and Whiting, and summing all dates. This method has an unevaluated error because it assumes uniform change in nesting numbers between spot censuses.

We calculated that during 1980 1,362 nests were excavated. Of these, 90% occurred on the primary nesting beach on Cape Sable. Nineteen of the crawls investigated led to nests, and 69% of these eventually suffered depredation.

Davis and Whiting (1977) calculated 1,644 nests were constructed in 1972 and 1,069 nests in 1973. The present estimate is midway between these. They found that 89% of the nests in southwest Florida occurred on Cape Sable and that predation destroyed 85% of the nests in 1972 and 75% in 1973. Comparison of these figures with our findings fails to reveal notable changes in the number of loggerhead turtles nesting in southwest Florida over the 1970s.

Raccoon predation is a principal cause of nest mortality among loggerhead turtles (Hopkins et al. 1978). Work by R. Klukas (pers. comm.) demonstrated predation could be reduced by removal of raccoons. Stancyk et al. (1980) reported that transplanting partially depredated nests was also effective. Davis and Whiting argued reasonably that such interference was inappropriate in a National Park where a policy of nonintervention holds, especially if nesting numbers were increasing. Others have questioned such a policy for a threatened species (A. Carr pers. comm. to G. E. Davis). A primary management concern should be whether raccoon numbers along the nesting beaches are artificially elevated above a natural level. This question cannot be resolved because there has been no study of raccoon population density on Cape Sable.

Although there is no evidence of decreased loggerhead turtle nesting in the study area, there is also no suggestion of the population increase predicted by Davis and Whiting. It should be noted too that the total population figure reported by Davis and Whiting depended on one very large count, which influenced the interpolations. The precision of the survey method is not known, and it is not possible to know what sort of change in nesting numbers would be detectable statistically. The use of airplane surveys for monitoring this population of turtles should involve the determination of its precision, and its accuracy. Institution of an accurate monitoring program and evaluation of the natural role of raccoon predation are essential for the conservation of this nesting population of sea turtles.

I would like to acknowledge the efforts of Richard Klukas and Gary Davis for providing the base line studies of Cape Sable sea turtles, which made the present comparison possible, and for their encouragement of our follow-up study. I especially acknowledge the efforts of my assistants Oron Bass and Todd Steiner in carrying out the field work, and Richard Dawson for his advice. The censuses were sponsored by the National Park Service, in cooperation with the National Marine Fisheries Service.

BOOK REVIEWS

The Bacterial Diseases of Reptiles, by Richard Ross and Gerald Marzec. 1984. 114 pp. 23 color photos. Publ. Institute for Herpetological Research, P.O. Box 2227, Stanford, California 94305. Paper, $22.00.

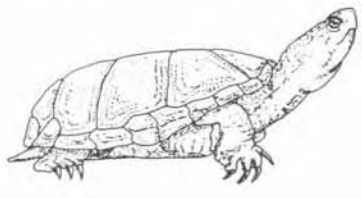
This book represents a major advance in herpetological husbandry techniques. Although the works of Reichenbach-Klinke, Frye, and Marcus are admirable and broad in their scope, they leave much to be desired in terms of practical diagnosis and day-to-day husbandry. Contrary to the opinion of some, these works are not *the end* in herpetological husbandry, nor, given the state of art, can they be. Ross and Marzec, however, have filled the gap admirably, at least as far as one disease syndrome is concerned.

Much of this work had its basis in field studies by the authors and in subsequent work in their laboratory. Some of their findings and recommendations will surprise some workers but I find little to argue with regarding their methodology and reasoning. Their finding that Gram-negative bacteria are the major causes of bacterial disease in reptiles is of particular interest and confirms my experience and that of many others. Their arguments for the use of aminoglycoside drugs in the treatment of these diseases are clear and forceful. These recommendations run counter to some current veterinary practices, but it would behoove all veterinarians to take them to heart.

There are other benefits to the book, though. The authors' recommendation that thermotherapy be used in conjunction with chemotherapy is to be applauded. There is evidence that allowing reptiles to raise their body temperature through "hot spots" serves the same purpose as a fever in homeothermic animals: initiation of an immune response by the ill animal (E. Jacobson, pers. comm.).

I was surprised to find that the authors recommend use of phenolic compound disinfectants, a practice largely discontinued upon the recommendation of Karl Kauffeld many years ago. That certain Gram-negative bacteria may actually grow in certain quaternary ammonium disinfectants, the type of disinfectant now most commonly used, is cause enough to make one consider reverting to phenolic disinfectants, in which Gram-negatives cannot grow.

Ross and Marzec's destruction of the theory that the snake mite is a major bacterial vector is gratifying. This role as a vector has never been proven to anyone's satisfaction, being based on one paper by Camin in 1948; yet the theory persists to this day. Ross and Marzec's laboratory work on snake mites taken from snakes with known infections of Gram-negative bacterial produced no evidence of those bacteria in the mites.



As we all know, with the good must come the bad, but my quibbles are minor. For instance, the authors state that, since the effects of aminoglycoside drugs are additive, half dosages of two different aminoglycosides cannot be administered. Why not? To the best of my knowledge, all injectable aminoglycosides have the same dosage: 2.5 mg/kg. Unless they are trying to say that different aminoglycosides act upon different bacteria (which may well be true), Ross and Marzec's statement makes no sense.

The authors give short shrift to gastroenteritis, a major disease syndrome in reptiles. In addition, contrary to their previous recommendations concerning Gram-negative bacteria and aminoglycoside drugs, the authors list a variety of non-aminoglycoside drugs to be used in treatment of this disease, which is normally caused by Gram-negative bacteria. The aminoglycosides, neomycin and spectinomycin, have been found to be very effective in treating this ailment. I also disagree with the authors' statements against the use of lincomycin, a non-aminoglycoside drug. I have found this drug to be particularly effective against cutaneous and subcutaneous staphylococcal infections.

I disagree with some of the authors' taxonomic designations. For example, the authors raise lampropeltine colubrids to familial level: Lampropeltidae. Although there may be merit in this, I have yet to see any definitive paper supporting this notion. Lastly, the authors commit a nomenclatural *non sequitor* almost equal to Ross' *Bothrochilus boa nardoana* of **The Python Breeding Manual**; this time it is *Liasis morelia spilotes!!*

All in all, though, the book is well worth its $22.00 purchase price. That may seem steep but perhaps this is justified by the several excellent color plates in the appendix. This book belongs in the library of anyone (particularly veterinarians) concerned with herpetological husbandry.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1986

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
		Institutional	$40.00

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Henri C. Seibert
SSAR Treasurer
Department of Zoological and Biomedical Sciences
Ohio University
Athens, Ohio 45701, U.S.A.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Commemorating the 50th Anniversary of *Herpetologica*

at

SOUTHWEST MISSOURI STATE UNIVERSITY

Springfield, Missouri

10-15 August 1986

Meeting Site

Southwest Missouri State University is a state supported, multipurpose institution with an enrollment of approximately 16,000. Students are drawn from throughout Missouri, from 45 other states, and from 25 other countries. Over 1,200 graduate students are enrolled in Master's and Specialist programs. The university is located in Springfield, Missouri's third largest city, with a population over 140,000. Springfield is located on the Ozark Plateau within easy driving distance of the most popular vacation and resort areas in the Midwest.

Technical Presentations

Research reports will be given in two formats: Oral presentations and poster sessions.

Special Herpetological Events

Distinguished Herpetologist Lecture (HL), 11 August.
A D. Dennis - J. E. Juterbock slide presentation (SSAR), 12 August.
A Regional Herpetological Societies' symposium-workshop on "The Role of Regional Societies in Public Education" (SSAR).
A Zoo Liaison Committee symposium-workshop on "Snake Venom Poisoning" (SSAR).
A symposium and workshop on "The Behavioral Ecology of Salamanders" chaired by R. Jaeger and K. Nishikawa (HL, SSAR).
Live herpetofaunal exhibits (SSAR).
Herpetology Examination coordinated by Marty Crump (SSAR).

Social Events

Sunday night social.
Monday evening graduate student social.
Tuesday evening Dennis-Juterbock slide show.
Wednesday evening BBQ and Auction.
Thursday evening banquet.

Displays (SSAR)

Numerous artists and exhibitors will display their work. For an exhibit application or further information contact:

Ruth Zantzinger
2108 Cherry Street
Philadelphia, Pennsylvania 19103, U.S.A.
(215) 557-0182

Field Trip

An all day float trip on the Niangua River, 15 August.

Collecting

Collecting is discouraged. Unless otherwise specifically exempted in the Wildlife Code of Missouri, all wildlife (including amphibians and reptiles) are protected by State law. Collection of wildlife (including herptiles) requires possession of a Wildlife Collector's Permit. For information write:

Missouri Department of Conservation
Wildlife Division
P.O. Box 180
Jefferson City, Missouri 65102, U.S.A.

Awards

Best student paper (HL).
Best student poster (HL).
Herp Examination prizes (SSAR).

Business Meetings

Inter-Society Liaison Committee Meeting 1930 h, 9 August.
SSAR Board Meeting, 1000 h, 10 August.
HL Board Meeting, 1300 h, 10 August.
Inter-Society Liaison Committee, 1200 h, 11 August.
SSAR Business Meeting, 1630 h, 12 August.
HL Business Meeting, 1600 h, 13 August.

Auction (SSAR)

This popular and traditional event will be repeated this year. Joseph T. Collins will be the auctioneer again. Proceeds will help support the meeting. Attendees are encouraged to donate books, art objects and other herpetological materials. Receipts will be given for all items sold (tax-deductible). Materials may be shipped to one of the meeting co-chairmen or brought to the meeting.

Accommodations and Meals

Dormitory apartments with linens and towels will be available at $10.00 per person per day. Each apartment has two or three individually locked bedrooms, a living room, kitchen, and bathroom. Needed floors will be designated for families and quiet areas. Blocks of rooms at discount rates have been reserved at two

motels within walking distance of campus. Reservations for these rooms will be made through the Local Committee. The rates for these motels are: University Inn, $26.00 per room per day; University Plaza, $50.00 per room per day. (Several of the social events will be held at the University Plaza. The University Inn is located on an adjoining property.) Numerous other motels are available but not within walking distance. Three campgrounds are located just outside the city limits within 20-25 minutes driving time from SMSU.

Registrants may eat in the cafeteria at the Campus Union. The package rate is approximately $35.00 for all meals. Individual meals cannot be purchased. Several eating establishments are within easy walking distance of campus. A list of these (and others) will be provided in the Program. Alcoholic beverages are served at several places within staggering distance of SMSU.

Family Meeting

Trip to Silver Dollar City
Luncheon and tour of Springfield
Trip to Dickerson Park Zoo
Trip to Wilson's Creek National Battlefield

Meeting Announcement

The official meeting announcement, call for papers, and preregistration forms will be mailed to all members in March. Those planning on attending are strongly urged to preregister since there will be a greater difference between preregistration and registration fees than in past years.

Transportation

Springfield, Missouri is accessible via several airlines, Interstate Highway 44, U.S. Highways 65, 160, and 60 and several state highways.

Meeting Co-Chairmen

Don Moll and Robert Wilkinson, Jr., Department of Biology, Southwest Missouri State University, Springfield, Missouri, 65804, U.S.A.

All interested persons are welcome to attend. Non-members may obtain programs and registration material by writing to the co-chairmen. ●

SSAR BUSINESS

SSAR ELECTION RESULTS

The results of the 1985 SSAR Election are as follows:
President-elect: Norman J. Scott, Jr.
Secretary: James S. Jacob
Treasurer: Henri Seibert
Board-Regular: Victor H. Hutchison
Board-Zoological Parks: William W. Lamar
A total of 531 members voted in the election.

The Society extends its gratitude to the Nominating Committee (Douglas H. Taylor, Chair), and to the SSAR Elector (David Grow) for their hard work, and to the outgoing President and Board Members for their service during their terms. ●

NEW SECTION EDITOR FOR LIFE HISTORY NOTES

We are pleased to welcome Dr. Peter J. Tolson as the new Section Editor for *Herpetological Review's* Life History Notes. Dr. Tolson is Curator of Reptiles at the Toledo Zoo, has previous editing experience, and has a broad knowledge of amphibian and reptile biology. Beginning immediately, all manuscripts for this section should be sent to Dr. Tolson at the Toledo Zoo (see inside front cover for address).

The Society extends its thanks to Bern Tryon for his many years of outstanding service as LHN Section Editor. Bern will continue as Section Editor for Herpetological Husbandry. ●

SSAR CONTRIBUTORS

Once again we are pleased to recognize those individuals who have financially aided the Society by becoming Contributing or Sustaining members for the year 1985 and also those who have supported the Grants-in-Herpetology fund. A statistical analysis would reveal a very high positive correlation between those who have contributed in 1985 and those who have contributed in previous years. To all of you, new or old, we offer our thank you. H.C. Seibert, Treas.

SPONSORSHIP OF NON-U.S. MEMBERS

SSAR is expanding its sponsorship of non-U.S. members by requesting contributions to a fund established to defray the membership dues of herpetologists in countries that face difficulties with exchange of foreign currency. We encourage your participation in this program. Please contact our Treasurer, Dr. Henri C. Seibert, if you can assist in the identification of colleagues who can benefit from this program. All contributions are tax deductible. ●

NEWSNOTES

ASIH SOLICITS WORKSHOP PROPOSALS FOR ANNUAL MEETINGS

At the 1985 annual meeting of the American Society of Ichthyologists and Herpetologists (ASIH) the Board of Governors of that Society approved a plan to have teaching workshops at future meetings. The Time, Place and Program Committee (TPPC) of the ASIH has been charged with soliciting workshop proposals. Proposals for the 1987 meetings are invited at this time.

Workshops, as defined here, are distinct from symposia in that they involve *hands-on experience*. A workshop should provide a more thorough and complete treatment of a method or topic than one would expect from a platform presentation. Participants in an ASIH workshop should be able to leave the workshop with the ability to carry out procedures learned there or to teach what they learned to others. Workshops may involve field and laboratory exercises in ichthyology and herpetology. They could be of a systematic nature and constitute a review — with specimens available for examination — of a major taxonomic group. The ASIH—TPPC is open to proposals in *all* areas of ichthyology and herpetology.

Each workshop should include a handout or syllabus. A typical workshop might run from 2 to 3 h and have 20 to 24 participants, although the ASIH—TPPC will consider applications for longer and larger workshops.

The ASIH Board of Governors has approved cash advances of up to $300 to cover expenses (e.g., syllabus preparation; shipping workshop materials to the meeting site) in setting up each workshop approved by the TPPC. It is hoped that these funds can be recovered in full or in part from registration fees for each workshop.

Those interested in organizing workshops for the 1987 (and future) meeting should submit their proposals to:

Workshop Program, ASIH—TPPC
c/o Richard Wassersug
Department of Anatomy
Dalhousie University
Halifax, Nova Scotia
CANADA, B3H 4H7

Workshop proposals should be no longer than three typed pages and must include brief statements on: the qualifications of the organizer(s), the size and length of the work-

shop, and the budget, if any set-up funds are requested. Proposals will be considered on a first come first serve basis. Students as well as senior members of the community are invited to submit proposals.

In order to assure a time slot in the program and funding, prospective workshop organizers should have their proposals submitted at least three weeks before the annual meeting of the year preceding the proposed workshops. All those interested in organizing workshops for 1987 should get their proposals to The Workshop Program, ASIH—TPPC, as soon as possible, preferably before 1 June 1986. ●

NIXON GRIFFIS FUND FOR ZOOLOGICAL RESEARCH

New York Zoological Society trustee Nixon Griffis has established a unique fund for zoological research. Open to zoo and aquarium scientific staff members across the nation, fund recipients may be curators, keepers, veterinarians, and research and consulting biologists. Programs to be considered for support include those in: animal behavior, veterinary medicine, reproductive biology, genetics, exhibition design and other research areas that address the care, management and propagation of wildlife in captivity.

Grants, not to exceed $3000, will be awarded biannually. For information about the Fund and grant applications, interested biologists are urged to write to:

The Nixon Griffis Fund
for Zoological Research
c/o New York Zoological Society
185th Street and Southern Blvd.
Bronx, New York 10460, U.S.A. ●

ALL FLORIDA CONFERENCE

The ALL FLORIDA HERPETOLOGICAL CONFERENCE AND SHOW will be held April 12-13 at the Florida State Museum, University of Florida, Gainesville, Florida. Registration and session information is available from Rhoda Bryant, (904) 392-1721. ●

ECOLOGY RESEARCH FELLOWSHIP

The **MORTON B. RYERSON FELLOWSHIP** has been established through funds contributed by the Chicago Community Trust. Applications are being solicited for fellowships-in-residence to begin in May 1986 or thereafter.

Open to any student, with preference to graduate students, the fellowship awards a monthly stipend of $800, plus room, for any period from two to nine months. Fellows are granted full and private use of a comfortable four-room log cabin with kitchen, spectacularly situated amidst floodplain, hardwood forest on the banks of the Des Plaines River in the Edward L. Ryerson Conservation Area, managed by the Lake County Illinois Forest Preserve District.

Fellows will be expected to conduct independent field research on any topic relating to ecology and/or conservation in northern Illinois forests. Cooperation with a local interpretive nature center is encouraged, but the research project is paramount.

Applicants should send a two to three page proposal, a resume or CV, two letters of recommendation, and a proposed schedule of residency at the Ryerson Conservation Area.

Address application or requests for complete fellowship description to:

DR. JOHN W. FITZPATRICK
Chairman
Morton B. Ryerson Fellowship Committee
Department of Zoology
Field Museum of Natural History
Roosevelt Road at Lake Shore Drive
Chicago, Illinois 60605, U.S.A.

Deadline for receipt of applications for the 1986 program was 15 February. Applications for next year's program are now being considered. ●

VOLUNTEER PROGRAM AT AMNH SOUTHWESTERN RESEARCH STATION

Approximately 20 volunteer positions are open this summer (1986) at the Southwestern Research Station of the American Museum of Natural History in Portal, Arizona. The volunteer program is run annually and offers students in the biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging at the Station are provided to volunteers in exchange for four hours per day of routine work chores, with the remaining time available for research activities.

Volunteers are needed each year between 10 March and 1 December and are appointed for part of this period, with a minimum appointment of four to six weeks. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Applicants for positions from March through May should submit forms by 15 February, summer volunteers, June through September, by 1 April. The program is open to both undergraduate and graduate students.

For application forms, write:

Resident Director
Southwestern Research Station of
The American Museum of Natural History
Portal, Arizona 85632, U.S.A.
(602) 558-2396 ●

SNAKE RESEARCH PROJECTS

The Irula Snake Catcher's Cooperative is a tribal self-help project based on catching snakes, extracting their venoms, marking and releasing them back to the wild. Last year about 22,000 snakes were caught and released, the majority *Echis carinatus*.

The Irula Cooperative is committed by its stated objectives to carrying out research pertinent to its activities of "passive exploitation" of snakes. Present data collection on distribution and abundance of snakes, scat analysis, sex ratios etc. are just some of the areas to be worked on.

The Cooperative is interested in collaborative research projects. As it is a tribal project it could provide basic facilities; funding would have to be provided by the collaborator.

For further information please write to:

LEGISLATIVE ALERT

Recent CITES Actions. The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) regulates trade in certain wild animal and plant species. At the Fifth Meeting of the Conference of the Parties to CITES (COP 5) held 22 April-3 May 1985 in Buenos Aires, Argentina, several species amendments to Appendices I and II were adopted and, effective 22 November 1985 (Federal Register), became incorporated into the U.S. Fish and Wildlife Service's regulations implementing CITES. Amendments of interest to herpetologists are:

1. Additions to Appendix II of the CITES list:

Nile crocodile *(Crocodylus niloticus)* populations in Cameroon, Congo, Kenya, Madagascar, Malawi, Mozambique, Sudan, Tanzania, and Zambia subject to export quotas described by the Secretariat.

Broad-headed snake *(Hoplocephalus bungaroides)*

Asian bullfrog *(Rana hexadactyla)*

Indian bullfrog *(Rana tigerina)*

Platypus frog *(Rheobatrachus* spp.)

2. Revisions of the CITES list:

Appendix I: **Nile crocodile** *(Crocodylus niloticus)*, except those populations in Appendix II (cf. above)

Appendix I: **Salt-water crocodile** *(Crocodylus porosus)*, except the population of Papua New Guinea, the Australian population subject to ranching, and the Indonesian population subject to export quotas. These three are, as of COP 5, now included in Appendix II.

Appendix III: **Monteverde toad** *(Bufo periglenes)*

A majority of the 66 countries attending COP 5 rejected all proposals to allow increased trade in world sea turtle products. As noted by the "Tortuga Gazette" reporting on the Center for Environmental Education's (CEE) Sea Turtle Rescue Fund (STRF), despite this display of concern for sea turtles, one of the major problems with the treaty still was not adequately addressed. This is Japan's continuing importation of large amounts of sea turtles and sea turtle products (40 to 70% of Japan's tortoise-shell each year has been provided by Indonesian hawksbills to supply the luxury market in Japan) without complying with Conference Resolution 4.25 requiring an importing country to obtain a certificate from an exporting country attesting that the shipment of wildlife products meets CITES standards. CEE and STRF urge concerned supporters to write to the Japanese embassy urging that Japan withdraw its res-

ervations to CITES and to comply with C.R. 4.25. The U.S. address is: Embassy of Japan, 2020 Massachusetts Ave., N.W., Washington, D.C. 20008, U.S.A.

Ban on Commercial Taking of ***Caiman crocodilus.*** Dr. Stefan Gorzula has forwarded an official notice from the Ministry of the Environment and Renewable Natural Resources of the Republic of Venezuela concerning *Caiman crocodilus*. Effective 23 October 1985, all commercial hunting of *C. crocodilus* is suspended in Venezuela for a period of one year in order to evaluate programs of commercial exploitation of this species that have been in effect.

Listing of ***Sternotherus depressus*** *as a Threatened Species.* United States Fish and Wildlife Service proposes to list the flattened musk turtle, *Sternotherus depressus* Tinkle and Webb (1955), as a threatened species (Federal Register 1 November 1985). Deadline for receipt of comments was 31 December 1985. The proposed action, if made final, would implement full protection of *S. depressus* under the Endangered Species Act of 1973 as amended. Federal agencies would be required to conserve the species, state agencies could enter into Cooperative Agreements, and, without a permit, it would be illegal for any person to take *S. depressus*, or to import, export, ship in interstate commerce, or sell or offer it for sale in interstate or foreign commerce.

The flattened musk turtle is found only in Alabama in the upper Black Warrior River system above the fall line. The U.S. Fish & Wildlife Service included *S. depressus* in a notice of review of the status of 12 species of turtles (FR 6 June 1977) and received information from a number of herpetologists who suggested that the flattened musk turtle should be listed as threatened. Detailed status surveys were conducted by Dr. Robert H. Mount in 1981 and by Drs. Carl H. Ernst, W. A. Cox, and Ken R. Marion in 1983. These studies have shown that only about 15% of the turtle's habitat contains healthy, reproducing, viable populations.

Chief factors threatening *S. depressus* are: (1) Siltation and water pollution from surface mining, forestry, agriculture, and industrial and residential sewage effluents. These factors extirpate or reduce the turtle's mollusk prey populations, physically alter its rocky habitats, and provide a substrate in which heavy metals or chemicals toxic to the turtles accumulate; and (2) Overcollecting. Because it favors clean, shallow water, *S. depressus* is highly vulnerable to overcollecting. The species has been listed for sale on several dealer price lists at prices above $80 each and large collections from particular streams or pools have been documented. Most of the formerly good populations have been considerably reduced in this way in recent years.

Application for Permit re. ***Uma inornata.*** Notice is provided persuant to the Endangered Species Act of 1973 as amended (Federal Register 18 November 1985) regarding an application from Riverside County, California, and nine cities therein, requesting a permit to take Coachella Valley fringe-toed lizards *(Uma inornata)*, a species listed as threatened, incidental to certain development and conservation activities proposed to be conducted in the area persuant to a multi-party agreement implementing the Coachella Valley fringe-toed lizard Habitat Conservation Plan (HCP). Copies of the application, its supporting documents, HCP, and implementing Agreement are on file at several locations including: U.S. F & W S Sacramento Office of Endangered Species, 2800 Cottage Way, Room 1823, Sacramento, California 95825, U.S.A. (916/484-4935); and Riverside County Planning Department, 4080 Lemon Street, 9th Floor, Riverside, California 92501, U.S.A. (714/787-6181). Comment period ended 30 days following date of publication (18 November 1985).

SOCIETIES

GOPHER TORTOISE COUNCIL

The Gopher Tortoise Council is a nonprofit, conservation organization dedicated to the perpetuation of the gopher tortoise *(Gopherus polyphemus)* and its many associates in their native habitat. *G. polyphemus* is the only land tortoise in eastern North America. The Council was formed in 1978 by a group of scientists, students, and environmentalists who shared similar concerns about the decline of gopher tortoise populations throughout the southeastern United States. The Council's efforts, while focusing on the gopher tortoise as a "keystone species," follow an ecosystem approach. Thus, the conservation of the tortoise in its native habitats (longleaf pine forest and related xeric habitats) is considered the key to protecting more than 100 other animals that depend upon the tortoise's burrow for shelter — e.g., the eastern indigo snake, gopher frog, and Florida mouse.

The Council maintains a representative in each of the six states in the tortoise's range (AL, FL, GA, LA, MS, SC) as well as having several active committees (e.g., education, conservation, management, research, publications). Annually the Council provides funds of ca. $400 to assist one or two students conducting pertinent research.

The Council meets yearly in Oct-Nov to share ideas, present research papers and reports, and to develop and instigate further means to achieve its goals. Members receive a quarterly newsletter as well as the *Proceedings* of the annual meeting.

Interested persons may learn more about the Council anc the tortoise by requesting a free brochure and sample newsletter from GTC secretary-editor, Mrs. Ellen B. Nicol, Route 1, Box 1367, Anthony, FL 32617. Those wishing to join the Council may do so by mailing a check (payable to the Gopher Tortoise Council) to that address for 1986 dues. Membership categories are: Regular, $10; Student, $5; Organization, $25; Contributor, $25; and Sustaining Member, $100+.

RAÎNNE-SOCIÉTÉ WALLONNE D'HERPÉTOLOGIE

The Society was formed on 9 September 1984. The Society's objective is to promote the study and principally the protection of Walloon herpetofauna (Walloon is the southern, French-speaking part of Belgium). The double aim will be pursued by:

- Enquiry into the vulnerability of the population
- Action based on public opinion
- Promotion of scientific research to develop a better knowledge of the herpetofauna
- Protection of species and their habitats

To these ends, the Society will take over land and equipment, exploit every resource, have useful regulations passed with the help of public opinion and of individuals and cooperate with organizations having objectives compatible with theirs.

Publication: A tri-annual revue, *Rainne.*
Chairman: Marcel Brialmont
(Rue D. Belleflamme 23,
B-4610 Beyne-Heusay, Belgium).
Administration: Christian Vansteenwegen,
Parc Naturelle de la Burdinale, Rue Onu 8,

BRITISH HERPETOLOGICAL SOCIETY MEETINGS 1986

Meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1, and start at 7:00 pm, ending at 9:00 pm, unless indicated otherwise. As always, *SSAR members* and other North American herpetologists visiting or on stop-overs in London *are most welcome.* For further details, please write to BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, England.

26 February

Dr. Andrew Gardner (Department of Zoology, University of Aberdeen, now Department of Genetics & Biometry, University College London): Herpetofauna of the Seychelles (Indian Ocean).

18 March

A.G.M. (see separate Agenda), followed by Dr. M.R.K. Lambert (Chairman, BHS): Some more herpetofauna of the Commonwealth. II. Ethiopian Zone *(as time allows).*

24 April

Dr. Paul Verrell (Department of Biology, Open University, Milton Keynes): Sexual cycles and breeding dynamics of smooth newts in southern England.

28 May

Conservation of rare herpetofauna and their habitats. Prof. G.A.D. Haslewood (Chairman, BHS Conservation Committee), with an Intro-

duction, and other members, including Keith Corbett (Chairman, Conservation Committee of Societas Europaea Herpetologica) and Tom Langton (Staff Herpetologist, Fauna & Flora Preservation Society, London), will describe current work of the BHS Conservation Committee.

19 June

**Amphibia and reptiles worldwide: their care and breeding.* A discussion organized by the Captive Breeding Committee (Chairman: Dr. Simon Townson).

July

Meeting and date to be arranged (see announcement in *BHS Bulletin*).

23 September

Topic to be arranged by the Captive Breeding Committee.

23 October

Conservation and ecology of Mediterranean tortoises. Dr. Ian Swingland (School of Continuing Education, University of Kent, Canterbury, and Chairman, IUCN/SSC Tortoise Group) and David Stubbs (Founder, Station d'Observation et de Protection des Tortues des Maures, France): Movement patterns in *Testudo hermanni* and implications for management. David Stubbs and Dr. Ian Swingland: Conservation efforts on *T. hermanni* in S France. Dr. M.R.K. Lambert: The pluviothermic range of Mediterranean *Testudo* and growth of captive bred hatchlings in the climate of N Europe in relation to conservation farming.

18 November

John Buckley (Member, BHS Conservation Committee): Natterjack conservation, including reintroductions, in East Anglia.

*Members are encouraged to bring live animals, preserved specimens and 35mm slides for display and to illustrate discussions. ●

SAN DIEGO TURTLE AND TORTOISE SOCIETY

The San Diego Turtle and Tortoise Society is a registered non-profit California corporation comprised of individuals sharing a common interest in Chelonians and is dedicated to the preservation of existing wild populations along with a better understanding and knowledge of care for those animals already in captivity.

The Society began in 1971 with a small group of people sharing a like interest in turtles and tortoises and has since grown to a membership of over 3000 individuals, both in the U.S. and many foreign countries. Monthly meetings take place on the 2nd Friday of each month at 7:30 p.m. in Room 101 of the Casa del Prado in Balboa Park, San Diego, California, at which time a formal guest speaker or presentation is offered, followed by an informal exchange of ideas and information on the "shelled" charges of our many members.

The Society has many committees and educational programs available and several of our local members are recognized authorities in their fields of turtle and tortoise care and research. A monthly news bulletin is published and mailed to the membership. It contains practical, up-to-date information on turtles and tortoises in the wild and in captivity.

The greatest emphasis of the Society is placed on the continuation and preservation of declining wild populations and many of its activities are directed toward organized conservation and education programs.

MEETINGS

SINO-JAPANESE HERPETOLOGICAL SYMPOSIUM

From 25 August to 5 September 1985, 90 herpetologists from four countries (China, Japan, U.S.A. and Switzerland) met at the Sino-Japanese Herpetological Symposium held in Guangzhou, China. It was the first time that the Chinese Society of Herpetology and the Herpetological Society of Japan cosponsored an international meeting for academic exchanges. Some 70 papers and reports were presented at the symposium, covering a wide range of topics, including taxonomy and fauna, ecology and evolution, physiology, morphology and ultrastructure, embryology, karyology, and snake venom and toxicology. To some extent, they showed results of current research and advances in these four countries.

The atmosphere that pervaded the host institution, the South China Normal University, was lively and cheerful throughout the symposium. Participants were active in exchanging information and ideas in their specialties. Many of them felt that such an informative meeting provided opportunities to discuss problems and observe developments in their research fields. It was also helpful for them to enhance academic ties and friendships through this symposium. Besides lectures and discussions, participants enjoyed a five-day survey tour to Hainan Island during the symposium period.

The Sino-Japanese Herpetological Symposium was a great success. It was a significant beginning for further communications among herpetologists of China and Japan, as well as other countries. This symposium will, as the sponsors believe, have a positive influence on promoting herpetological studies in China and Japan.

Abstracts of papers presented by Chinese herpetologists have been published in Acta Herpetologica Sinica, Vol 4(2), 4(3) and 4(4) 1985. Other proceedings will be published later.

EUROPEAN HERPETOLOGICAL MEETING

The 3rd Ordinary General Meeting of the Societas Europaea Herpetologica was held in Prague, Czechoslovakia, 19-23 August 1985, and was hosted by the Faculty of Natural Sciences, Charles University, Prague. It was attended by 261 herpetologists from 29 countries (Australia, Austria, Belgium, Brasil, Canada, Czechoslovakia, Cuba, Denmark, France, GDR, FR Germany, Greece, Hungary, India, Israel, Italy, Netherlands, Nigeria, Norway, Pakistan, Poland, Romania, Spain, Sweden, Switzerland, United Kingdom, USA, USSR, Yugoslavia). This seems to be the first herpetological meeting where so many countries were represented. Nearly 240 contributions were presented, either talks or poster presentations.

After an "ice-breaking" social held Sunday evening, the meeting began officially at 0900 h on Monday, 19 August. Zbyněk Roček welcomed participants on behalf of the local organizing committee, and Josef Eiselt gave his Presidential Address. After these brief opening ceremonies the meeting began with the lecture "The Origin of the Amphibia" given by Erik Jarvik from Stockholm. The first day was devoted to the problems of the origin and evolution of the Amphibia and Reptilia, from the viewpoints of both paleoherpetology and neoherpetology.

On Tuesday 20 August, the morning business session dealt with affairs of the SEH. The scientific programme of the meeting consisted of 12 sessions on Systematics, Ecology, Physiology, Genetics, Morphology and Ontogeny, Behaviour, Distribution, and Conservation, and a "mini-symposium" on *Podarcis*.

Besides the scientific programme, one of the goals of the organizers was to provide an opportunity for informal meetings among the people from different countries.

All participants and their guests were invited into the Aula Magna of the Carolinum, the oldest university building preserved on the European continent, to listen to the concert of old Czech music. The programme "Music in the Reign of Czech Kings" was performed by musicians playing medieval musical instruments. This music, composed in 14th to 17th centuries, is appreciated even by herpetologists living in 20th century, as shown by the hearty ovations. During the evening, the participants were welcomed by Prof. František Fabian, Dean of the Faculty, and by Prof. Vladimír Pokorný, Vice-president of the Czechoslovak Academy of Sciences. They were followed by Dr. Josef Eiselt, former SEH President, and Prof. Benedetto Lanza, new president of the Society. The evening was appreciated as one of the social highlights of the meeting.

On Wednesday, two excursions were organized to see some herpetological localities, as well as some historically interesting sites. The first led to south Bohemia, a pond area where an historic municipal reservation and several localities of local herpetofauna were visited. The itinerary of the second excursion included an excavation site of Palaeozoic amphibians, a walking tour of the

Participants in the 3rd Ordinary General Meeting of the Societas Europaea Herpetologica

subterranean karst labyrinth, a trip to the famous battlefield Slavkov (Austerlitz) known from Napoleonic history, and finally dinner in a wine cellar, with live folk music.

The social programme of the meeting was concluded Thursday evening in the famous Prague beer restaurant "U Fleku." The meeting was officially closed on Friday evening, 23 August by Benedetto Lanza, SEH President, and by some representatives of national herpetological societies.

It was decided to publish proceedings of this meeting in which most of the contributions (nearly 160) will be printed in full. The volume should appear in 1986 under the title "Studies in Herpetology," and can be ordered from:

Faculty of Natural Science
Library (knihovna)
Albertov 6
CS-128 43 Praha 2
Czechoslovakia

The meeting was generally appreciated as an opportunity to make personal contacts with those colleagues who are unable to participate in herpetological meetings in western countries. It also served as a basis for future cooperation with them.

FEATURES

ENVENOMATION BY A BLUESTRIPE GARTER SNAKE, *Thamnophis sirtalis similis*

Envenomation in humans has not been reported for *Thamnophis sirtalis similis*. Gans (1978) and Vest (1981) reported envenomation from the bite of *Thamnophis elegans terrestris* (originally misidentified as *T. couchi*) and *Thamnophis elegans vagrans* respectively. This phenomenon has also been reported from *Rhabdophis tigrinus* (Minton 1978) and *R. subminiatus* (Mather et al. 1978).

A large female specimen of *Thamnophis sirtalis similis* (64 cm total length) was given to me in the summer of 1982. Collection locale was unknown but was probably Pasco Co., Florida. The snake was removed by hand from its container. When restrained, it immediately bit the lateral surface of my right hand and chewed. To prevent damaging the snake by forceful removal, I permitted it to disengage spontaneously, which occurred after three min.

The finger displayed four distinct rows of punctures from the maxillary and pterygoid dentition. The wounds bled profusely for several min. The blood then coagulated normally. Thirty min after the bite, however, the finger was markedly edemetous (far more than could be attributed to the action of the teeth). Cyanosis around the wound progressed until, by the end of one h, the entire finger was discolored. Additional symptoms experienced were: moderate arthralgia, peripheral numbness in the digit, and lymphadentitis of the axillary nodes.

Fifteen h after the bite the edema had subsided considerably, the cyanosis and lymphadentitis persisted for an additional 72 h. The symptoms appeared and progressed far too rapidly to be attributed to bacterial or fungal infection, and no secondary infection developed.

Minton (1978) pointed out the possibility of acquired anaphylaxis to snake saliva. However, no urticaria developed in this case, nor were there any symptoms from previous or subsequent bites by natricine snakes. It is possible that the bite was a feeding rather than defensive response, as I had been handling mice earlier in the day. Residual odor may have precipitated the unusually lengthy bite response. This and other reported cases of natricine envenomation suggest the need for further biochemical analysis of saliva.

OVERWINTERING OF AN AMBYSTOMATID SALAMANDER IN A PRAIRIE RATTLESNAKE HIBERNACULUM

The tiger salamander, *Ambystoma tigrinum* (Green) is widely distributed over southern parts of western Canada and most of the United States. Currently, seven subspecies are recognized (Hassinger et al. 1970). There have been numerous studies of this salamander, principally from the United States, major ones being Powers 1907; Prosser 1911; Bishop 1943; Glass 1951; Murphy 1953; Gehlbach 1965, 1967; Tihen 1969; and Rose and Armentrout 1976. In western Canada however, little information exists on this salamander. It is known that very dry areas have populations that breed without transforming from larva to adult where there are suitable ponds or lakes for overwintering. But even in some arid areas they do transform, using heavy rains to migrate from ponds in late summer or fall, and spring rains to migrate to and from breeding ponds (Sprules 1974). There are advantages to each of these two strategies: the salamander can live where water sources dry up during summers and can also live where land is too dry to traverse in others. This may partially explain why *A. tigrinum* are the only salamander found between the foothills of Alberta and Manitoba.

Adult salamanders are known to spend considerable time during dry seasons in burrows of mammals (Seton 1918; Stebbins 1951). Stebbins (op. cit.) stated that use of underground retreats probably has been important in making it possible for this species to inhabit semi-arid regions. This note is the first report of use of a rattlesnake hibernaculum for overwintering by *A. tigrinum* in Canada or the United States.

On the morning of 25 April 1983, 2.7 km south of Lethbridge, Alberta, Canada, I caught a 17 cm (total length), 25.2 g blotched tiger salamander, *A. t. melanostictum* in a trap designed to catch prairie rattlesnakes *(Crotalus viridis viridis)* as they emerged from a hibernaculum. The length is within the size range considered by Smith (1949) and Preston (1982) as mature.

The hibernaculum entrance opened on a south-facing slope, 550 m from the closest surface water, the Oldman River. The adjacent land lies at an average altitude of 900 m and is open, dry and very hilly (slopes average 43° incline). Soils are sandy-clay and vegetation consists of drought-resistant herbs such as pasture sage *(Artemisia frigida)*, cushion cactus *(Coryphantha vivipara)*, prickly pear cactus *(Opuntia polyacantha)* and moss phlox *(Phlox hoodii)*.

Spring emergence by tiger salamanders from subterranean retreats usually occurs at night for feeding and migration to water for breeding (Goin and Goin 1971; Conant 1975). The tiger salamander left the rattlesnake hibernaculum sometime during the night of 24-25 April (the trap had been checked the evening of the 24th). The morning of the 25th was cloudy and 14° C. The trap had been set 6 March while there was still snowfall on the ground making it unlikely the salamander had already emerged for mating prior to its capture. Also, the cloacal region was strongly protuberant at the time of capture which is characteristic of a breeding male (Stebbins 1951). When the salamander was released 5 hours after capture, it immediately crawled back down the den and was not seen again. Two prairie rattlesnakes were captured from the same hibernaculum three days later.

Lewin (1963) stated that 141 of this subspecies were captured in the spring within 90 m of the shores of Pakowki Lake, southeast Alberta and were common in temporary and permanent lakes, ponds and roadside ditches. However, Lethbridge lies in one of the sunniest and windiest areas in Canada and similar water sources are very limited or non-existent due to rapid evaporation. Average annual precipitation ranges from 30-40 cm but only 22 cm falls during the growing season. As a result, tiger salamanders are not common in the Lethbridge area.

Oxybelis brevirostris (COPE): AN ADDITION TO THE SNAKE FAUNA OF HONDURAS

Wilson (1983) listed two species of *Oxybelis*, *aeneus* and *fulgidus*, as occurring in Honduras. In May of 1977, the senior author collected a specimen of *Oxybelis brevirostris* (Cope), 1860, on Cerro El Viejo, near the Río Platano in the department of Gracias a Dios, Honduras. This specimen represents the first record for the species in Honduras.

Peters and Orejas-Miranda (1970) gave the range of *Oxybelis brevirostris* as "Caribbean lowlands of Central America from Nicaragua through Panama to Pacific lowlands of Colombia and Ecuador." Boulenger (1896) listed a specimen from Chontalez (= Chontales), Nicaragua. This locality must refer to the department of Chontales; there is no city by that name in the country. Another Nicaraguan specimen (AMNH 75429), heretofore unreported, was collected at Musawas, on the Huaspac River in the northern portion of the department of Zelaya (George Foley, pers. comm.). Actually, Musawas is on the Haspuc River, a tributary of the Huaspac River.

The Honduran locality is approximately 175 km north of the Musawas locality. These two localities provide confirmation for the extension of the range of this rainforest species across the Nicaraguan depression into Nuclear Middle America.

The specimen (KU 195564) is a female exhibiting the following characteristics: 175 ventrals; 170 subcaudals; anal plate single; dorsal scale reduction pattern,

$$15\ \frac{3+4(135)}{3+4(134)}\ 13;$$

6-6 supralabials, 3rd and 4th entering orbit; 8-8 infralabials, 5th largest, four touching anterior chinshields; loreal absent; 1-1 preoculars; 1-1 postoculars; 1+2/1+2 temporals. In preservative the dorsum is purplish brown and the venter pale purple. The lower edges of the temporals are dark, giving the impression of a narrow, diffuse postocular stripe. These data are in agreement with those presented for this species by Boulenger (1896).

ACKNOWLEDGMENTS

My sincere thanks go to Jaime Villa, for informing me of the existence of the AMNH specimen, and to George Foley, for kindly sending me information on this specimen.

SKIN INFECTION IN HATCHLING RIDLEYS, *Lepidochelys olivacea* (ESCHSCHOLTZ), IN CAPTIVITY

While we were rearing the olive ridleys, *Lepidochelys olivacea* (Eschscholtz) at Bhagabatpur Crocodile Rearing Centre, Sunderbans, West Bengal, an outbreak of skin infection among infant olive ridleys was observed. The infection first appeared on 19 June 1983 as small yellowish patches on the neck and flippers of a month-old hatchling. It was found that almost all the 13 hatchlings were severely infected within three days. The infected areas increased in size while the disease was invading other sites, viz., eyelids and the carapace. The usual feeding schedule with fish, prawn and molluscan flesh (Banerjee 1984) was continued during the period of infection though the turtles showed a loss of appetite.

The affected areas were bathed once a day with aqueous 0.4% potassium permanganate solution after which the sites were cleaned with a soft brush. Most of the patches diminished within 4 days. Application of potassium permanganate solution was continued for another 3 days but no further improvement was noted. Following the advice of a local veterinarian the hatchlings were dipped in 0.08% aqueous solution of Terramycin antigerm-77 (Pfizer Limited, Thane, India) for 15 min, following the potassium permanganate applications. These treatments were repeated on every alternate day during the course of infection. In addition to the above treatment, the turtles were fed Electral® powder [The Fairdeal Corporation (Pvt.) Limited, Secunderabad, India] dissolved in water (5%) twice daily to revitalise them and to induce food intake. Electral® powder is a mixture of calcium lactate, potassium chloride, magnesium sulphate, sodium chloride, sodium acid phosphate, sodium citrate, permitted colour tartrazine, and dextrose.

The hatchlings responded to the treatment well. The skin infection disappeared completely by 6 July 1983. But about a week later, a hatchling without any sign of skin infection showed retarded growth in comparison to others and died on 16 August 1983. It had stopped feeding for 24 hours before its death. Postmortem study could not assign the cause of death. Another hatchling with stunted growth and bifurcated fore-flippers was again infected on 3 March 1984. Since the symptoms were similar to those described above, the same treatment was followed. The skin infection disappeared within a fortnight but soon the turtle stopped feeding and died on 12 April 1984. The postmortem study revealed enlargement of liver.

Whitaker (1978) reported a similar type of skin infection caused by fungus at the Madras Snake Park Trust when hatchling ridleys were 7 weeks old. He held that the disease had posed the biggest problem for turtle farming as it could cause death in serious cases of infection around the eyes and cloaca. In the present study, though the skin disease was successfully treated twice within a period of a year, the death of two hatchlings due to liver enlargement or other reason soon after the disappearance of the skin infection is still a problem. The literature shows that skin infection in reptiles may be due to attack by fungi, viruses, bacteria and helminths (Cooper and Jackson 1981). However, the role of bacteria in initiating skin infection in sea turtles is not clear. Though the causative agents were not isolated in the present study we believe they were bacteria, possibly more than one strain, some sensitive to potassium permanganate solution and others to terramycin.

Plectrohyla glandulosa (BOULENGER): AN ADDITION TO THE ANURAN FAUNA OF HONDURAS

The number of species of the hylid frog genus *Plectrohyla* known from Honduras has increased markedly since Meyer and Wilson (1971) listed *P. guatemalensis* as the sole species. The current total is four species (McCranie and Wilson 1981, 1985; the present paper) and two others remain to be reported, including an undescribed form.

On 26-27 April 1982 we collected several specimens of *Plectrohyla glandulosa* (Boulenger), 1883 (KU 195455-62) at an elevation of 2490 m on the east slope of Cerro Celaque (14°32'30"N, 88°40'W), Honduras' second-highest mountain (2827 m), in the department of Lempira. Adults were collected on low vegetation along a small stream in cloud forest vegetation.

The adults had the following color in life: lime green dorsum; pale maroon side; dark stripe from nostril to eye to above tympanum.

Duellman (1970) gave the range of *P. glandulosa* as "elevations from 2400 to 3500 meters in the highlands of Guatemala and adjacent El Salvador." The Honduran locality is ca. 60 km ENE of the nearest locality in El Salvador.

COMBAT BEHAVIOR IN THE GILA MONSTER *(Heloderma suspectum cinctum)*

Although reproductive behavior in *Heloderma* is well-documented (Peterson 1982) no description of combat behavior is found in the literature. On the morning of 6 January 1984 in an exhibit at the Reptile House of the National Zoological Park, two male *Heloderma suspectum cinctum* were observed in ritualized combat behavior. Both animals had been housed in the same exhibit with three male and one female *H. s. suspectum* for approximately two years. The exhibit is constructed of two 1.2 m x 1.2 m x 2.7 m glass-fronted enclosures joined at ground level by a tunnel constructed of rock and cement with a sunken pool on one side and several rock planters for shelter. Sand serves as a substrate. In addition to daylight from overhead skylights, supplemental lighting is provided by two 4-bulb banks of 40 W Chroma-50 fluorescent bulbs (G.E.) and a 400 W mercury vapor lamp (Sylvania) over one cage. Each cage also has a 150 W Plant Light (G.E.) placed 1.4 m over the floor to provide additional heat and light for basking. The animals are maintained at a year-round ambient temperature of 28° C, although it is warmer directly under the Plant Lights.

We rely upon a combination of three characteristics to determine sex of these lizards: The head at the widest point is generally smaller in females (46.4-51.0 mm in our sample of ten) than in males (52.0-57.3 mm), cloacal probes penetrate less deeply in females (12-23 mm) than in males (15-32 mm), and the presence of a 10-12 mm long bulge just posterior to the vent of females, particularly noticeable in side view. The bulge appears to be absent in males. Three of our *Heloderma* have laid eggs and fall well within these parameters. One of the ten animals was questionable due to a shallow probe depth, however a large head width and lack of a post-anal bulge leads us to think it is a male.

All observations were made in the exhibit cage. The animals were first seen interacting at 0800 h and continued throughout the day until about 2000 h when note taking ceased although the animals continued to interact. Observations were intermittent with spot checks at least every hour. The next morning the combat had stopped and all animals were acting normally. The combat consisted of almost continual "bouts" described in this paper. A bout refers to an interaction between the two males from the time of approach to when they disengaged. The larger lizard (900 g, 350 mm SVL) appeared to dominate the smaller (750 g, 330 mm SVL), although there were several dominance shifts. The lizard in the superior body position at the end of the bout was considered to be dominant. The other lizards in the cage did not participate in the combat and showed no outward signs of interest or disturbance. One of the three non-participating males was, however, with no apparent provocation bitten on the leg, held, and shaken for about two minutes by the largest combatant. When the aggressor released his grip, the other lizard retreated into a corner and offered no resistance or rebuttal.

Ten major behavioral acts were identified:

FRONTAL HEAD NUDGE - Pushing the snout against another lizard's body or head.

LATERAL HEAD SHOVE - Pushing another lizard's head or body with a lateral movement of the head.

DORSAL HEAD PIN - Forcing an opponent's head downward with the chin from a lateral or head on position.

DORSAL STRADDLE - Mounting the back of an opponent. Usually involves gripping the inferior lizard on both sides of the body with the front and rear legs.

NECK ARCH - Upward arching of the neck by the inferior lizard. Performed when a combatant has effected a DORSAL HEAD PIN.

TAIL WRAP - Intertwining of both combatants' tails while in a DORSAL STRADDLE position.

LATERAL TAIL THRASH - Vigorous sideways movement of the tail by the superior lizard in the DORSAL STRADDLE position.

TAIL WAVE - Lateral movement of tail by inferior lizard while PINNED or in a partial DORSAL STRADDLE.

LATERAL HEAD BITE - Vigorous open-mouthed swipe by the superior lizard in a DORSAL STRADDLE position. Performed simultaneously with a LATERAL TAIL THRASH, in the same direction as the BITE.

ROLL - Turning over the inferior lizard from a DORSAL STRADDLE position by the superior lizard.

TYPICAL SEQUENCE OF COMBAT ACTS

A typical sequence of combat acts was determined qualitatively. The aggressor, usually the same animal, would often instigate the bout by nudging the other lizard, sometimes coming under the body to lift the opponent off the ground. HEAD NUDGING could be preceded, but was usually followed, by LATERAL HEAD SHOVING. This was done when the animals were laterally oriented toward each other. LATERAL HEAD SHOVES were performed by either lizard, often in response to a previous SHOVE.

These initial acts were often followed by a DORSAL HEAD PIN by one of the lizards, which elicited a NECK ARCH (Figure 1) from the opponent. A DORSAL HEAD PIN was often broken by a NECK ARCH; if not, the aggressor could move into a DORSAL STRADDLE position (Figure 2). DORSAL HEAD PINS were usually executed from a lateral position whereas a STRADDLE was more often associated with a rear approach. Some circling occurred during these encounters but usually the aggressor would simply approach and STRADDLE his opponent.

NECK ARCHES did not seem to be very effective against a fully-executed DORSAL STRADDLE hold which included a tight grip with both legs and a TAIL WRAP. In this position the inferior animal's tail was slightly raised and the aggressor's tail firmly pressed against it. If the tails were not tightly entwined during the DORSAL STRADDLE a TAIL WAVE was often performed by the inferior lizard. The inferior animal also TAIL WAVED when under a DORSAL HEAD PIN.

From the DORSAL STRADDLE position with tails locked the superior lizard would often attempt a LATERAL HEAD BITE, simultaneously THRASHING the tail in the direction of the BITE. Although no attempt was made to hold on, both lizards had bruised areas around the head and labials as a result of this behavior. The vigorous LATERAL HEAD BITING and TAIL THRASHING served to bend the inferior lizard into a crescent shape. The aggressor might do this several times before the action either dislodged him or effected a ROLL. A ROLL occurred as the inferior lizard reached the limit of his lateral bend. The aggressor then would pull on the inner side of the other's body with his legs and manage to flip both of them over on their backs. The reason for this behavior is unclear

Figure 1. Two male *Heloderma* in combat ritual. Superior animal has a DORSAL HEAD PIN on opponent which is responding with a NECK ARCH. Other lizards in picture are non-participants in the combat.

Milwaukee Public Museum

As an award-winning publisher, we are proud to offer reference publications for the specialist. The new edition of *Snakes of Honduras* and the recently published *Amphibians and Reptiles of the West Indies*, contain superb color illustrations not found elsewhere. Write or call today for your free catalog, and find out why herpetologists rely on us for excellence in publications. Manuscript queries welcome.

Just Released

Snakes of Honduras, 2nd Revised Edition
Larry David Wilson, John R. Meyer
ISBN 0-89326-115-7 160 pages *$29.95*
The new edition of this important reference includes color photographs of selected species and black and white habitat photos. For each of the 95 species of snakes found in Honduras Wilson and Meyer have included a partial synonym, geographic range, description, ecological distribution, locality records and maps. Dichotomous keys for the identification of the families, genera and species are included. Patterns of present-day distribution with respect to physiographic regions, elevation and vegetational types are examined, and a gazeteer of Honduran localities not previously published is appended. Extensive literature list, Spanish resumen.

Guide to the Identification of the Amphibians and Reptiles of the West Indies (exclusive of Hispaniola)
Albert Schwartz, Robert W. Henderson, 1985.
ISBN 0-89326-112-2 176 pages *$29.95*
Finally, a book that allows biologists to identify West Indian amphibians and reptiles. The identification keys direct users to species accounts that list subspecies (if known to occur), the key literature which will provide additional descriptive or distributional information, and distribution.

- Identification keys to 370 species occurring in the West Indies.
- Extensive bibliography with nearly 1200 entries.
- Geographic coverage of the Bahama Islands, Cuba, The Turks and Caicos Islands, Jamaica, Puerto Rico, the Virgin Islands the Lesser Antilles.
- Over 100 taxa illustrated in color.
- A perfect companion volume to *Amphibians and Reptiles of Hispaniola* by the same authors.

A Guide to the Amphibians and Reptiles of Hispaniola
Robert W. Henderson, Albert Schwartz, 1984.
ISBN 0-89326-103-3 76 pages *$6.95*
An important guide to identifying species in this area. Keys, literature cited, map, glossary. Color cover and 16 black and white photos.

Venomous Snakes of Nicaragua
Jaime Villa, 1984.
ISBN 0-89326-107-6 42 pages *$6.95*
Several new species and keys to identification. Color photos, maps, illustrations. Spanish resumen.

Ecological and Taxonomic Notes on Nicaraguan Anoles
Henry S. Fitch, Richard A. Seigel, 1984.
ISBN 0-89326-104-1 14 pages *$4.95*
Fourteen species of Anolis are recorded from Nicaragua. Spanish resumen.

***Anolis Cybotes* (Reptilia, Iguanidae): The Eastern Hispaniolan Populations**
Albert Schwartz, Robert W. Henderson, 1982.
ISBN 0-89326-079-7 8 pages *$2.50*
A new subspecies of *Anolis cybotes* from Isla Saona, República Dominicana, is described.

A Review of the Colubrid Snakes of the Genus *Tantilla* of Central America
Larry David Wilson, 1982.
ISBN 0-89326-082-7 78 pages *$10.00*
Taxonomy and distribution of seventeen species of the colubrid snake genus *Tantilla* known to occur in Central America. Maps, geographical variation, ecological data, key to identification. Well illustrated with black and white photographs.

The Cuban Lizards of the Genus *Sphaerodactylus* (Sauria, Gekkonidae)
Albert Schwartz, Orlando H. Garrido.
ISBN 0-89326-109-2 68 pages *$6.95*
Variation, distribution, and ecological information are presented on all species and subspecies.

Other titles available. Free catalog on request. Domestic orders please add $1.50 shipping for first title, 25¢ for each additional title; foreign orders, add $2.25 for first publication, 30¢ for each additional title. Scholars receive 10% discount if order placed on institution's letterhead. Phone orders accepted for Visa and Mastercard charges.

Figure 2. Two male *Heloderma* in combat ritual. Superior animal is in a DORSAL STRADDLE position over opponent.

since it resulted in the dominant animal ending up underneath. At this point both animals would disengage and a similar sequence would commence, beginning with an approach by one of the lizards followed by either LATERAL HEAD SHOVING or HEAD NUDGING.

DISCUSSION

This was the first indication of combat in these animals during the three years they have been housed together. *Heloderma* combat had been observed at the Houston Zoo in 1983 (Karl Peterson, pers. comm.). In one instance, a larger male bit another so forcefully as to lift him off the ground, whereupon they were separated.

Several behaviors were exhibited primarily by the dominant lizard (HEAD PIN, STRADDLE, TAIL THRASH, HEAD BITE, and TAIL WRAP) while others (NECK ARCH and TAIL WAVE) were observed only in the subordinate lizard. The latter were usually performed in response to acts by the dominant lizard. The main objective seemed to be to push the opponent to the substrate and keep him pinned there. In this respect, the behavior is strikingly similar to the ritual male-male combat of varanids in which the primary features are centered around a test of strength in which the opponents wrestle or grapple and attempt to force the other to the substrate (Auffenberg 1981). The *Heloderma* combat is different from varanid combat in that the grappling is dorso-ventral rather than ventro-ventral and the general *Heloderma* orientation is horizontal instead of bipedal. With the exception of *Varanus gilleni* (Carpenter et al. 1976b) ritual varanid combat does not include biting, whereas the *Heloderma* combat did.

Some aspects of the *Heloderma* combat such as the DORSAL HEAD PIN, DORSAL STRADDLE, LATERAL HEAD SHOVE, TAIL WRAP and NECK ARCH seem to be similar to behaviors noted for some snakes, such as topping, pushing, and entwining for crotalids (Carpenter et al. 1976a) and dorsal pin and head raise for *Elaphe obsoleta* (Gillingham 1980). A predominant feature of the *Heloderma* combat is the strongly ritualistic nature of the behavior as noted for varanids (Carpenter et al.1976b) and crotalids (Carpenter et al. 1976a). Achieving a PIN or ROLL did not terminate the combat; the two males repeatedly and consistently re-engaged each other. During the entire combat they did not seem (to the observer) to be aware of or distracted by any outside activity or disturbance.

This highly ritualistic and tactile behavior is remarkably different from that of other lizards, notably agamids and iguanids in which no grappling occurs and most agonistic behavior consists of posturing and head bob displays (conspicuously absent in helodermatids and varanids). This would seem to lend behavioral support to morphological evidence (Camp 1923) that helodermatids and varanids do indeed belong to the same group that gave rise to the snakes.

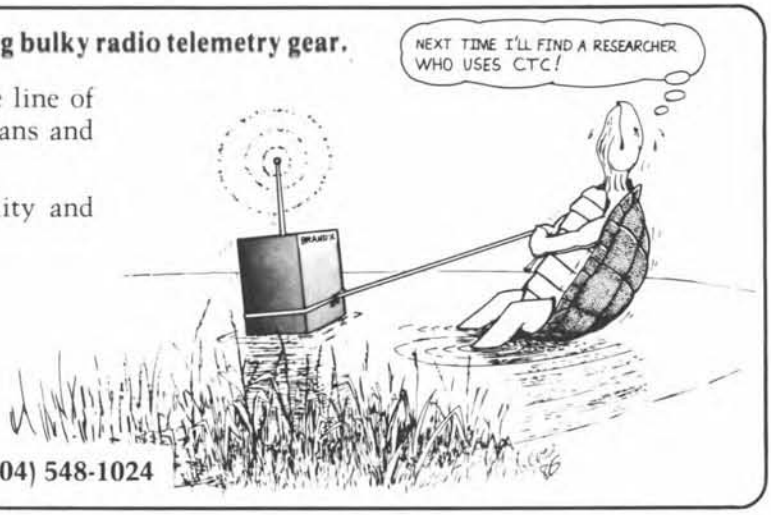
Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.



Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

No species of study should be burdened with carrying bulky radio telemetry gear.

Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

Custom design, high quality components, reliability and reasonable prices...that's *CTC*.

Please inquire for more detailed information.

CAPTIVE REPRODUCTION OF THE MUSSURANA, *Clelia clelia* (DAUDIN) FROM COSTA RICA

Little information about the reproductive cycle of the neotropical snake *Clelia clelia* has appeared in the literature.In his reviews, Fitch (1970, 1982) did not include information about reproduction in this species. Recently, Nickerson (1979) reported a female *C. clelia* that died before completing oviposition; the eggs were exposed to adverse conditions, and none hatched. Here we describe some aspects of the reproductive cycle of *C. clelia* from Costa Rica.

At the serpentarium of the Instituto Clodomiro Picado, a 200 cm long male and a 266 cm long female were put in a wooden cage measuring 1.22 m X 62 cm X 60 cm on 25 November 1982 at 0845 h. The temperature was 25° C and the relative humidity was 60 percent. Both individuals were collected in Salitrales, Puriscal, at an altitude of 1090 m in the province of San José. The male arrived at the serpentarium in May 1979 and the female in June 1980. Upon introduction, it was observed that the female was more aggressive toward the male, however, several minutes later the male was very active, crawling over the female's back and lying parallel to her body. An increase of tongue flicking was observed in both specimens. The male lifted his tail several times, pressing his cloaca against her body.

On two occasions the male everted one hemipenis, and copulation occurred at 0958 h, lasting 18 min. Several days after copulation, the female began to refuse food. A progressive increase in the size of the posterior part of her body was noted. Shedding occurred on 31 December 1982. Oviposition of ten eggs (some adherent) took place on 10 January 1983, 47 days after copulation. Nine eggs appeared in good condition; one was abnormal, with a yellowish color and a hard shell. They were weighed, measured and numbered. The length of the eggs ranged from 5.5 to 6.6 cm ($\bar{X}$ = 6.08 cm; SD = 0.37); the width ranged from 3.2 to 3.9 cm ($\bar{X}$ = 3.48 cm; SD = 0.20); and the mass ranged from 24.35 to 40.20 g ($\bar{X}$ = 36.73 g; SD = 5.85). The eggs were incubated in a fiberglass case 21 X 21 cm with dampened cotton on the bottom. The case was kept inside a plastic bag, and was opened daily for ventilation. Temperature was maintained in a range of 26-28° C in the incubator. The eggs hatched between 6-9 May 1983 after 117-120 days of incubation (Table 1). Two eggs did not hatch; when these eggs were opened, it was noted that the snakes were totally developed and dead, both possessing teratogenic malformations dorsally in the posterior part of the body.

Data on the young are given in Table 1. Coloration was transparent white ventrally and bright red dorsally except for neck and head. A black irregular spot was found on the neck followed by a well defined white ring that extended to varying parts of the parietal scales while totally covering the temporal scales. A black hood covered the anterior part of the head. Coloration was almost identical in all of the snakes. The ontogenetic changes that occur in the coloration pattern are under study and will be reported in another communication.

ACKNOWLEDGMENTS

The authors thank Ingrid Peña, Dr. José Maria Gutiérrez and Dr. Douglas Robinson for their help in preparing the manuscript.

A CAPTIVE BREEDING OF THE GREAT BASIN GOPHER SNAKE, *Pituophis melanoleucus deserticola*

On 15 October 1981, a pair (male-SVL 113 cm, mass 482 g; female-SVL 110 cm, mass 300 g) of *Pituophis melanoleucus deserticola* was received at the Cheyenne Mountain Zoo. Both snakes were long term captives that had been housed together, and had exhibited no previous reproductive behavior. Upon arrival at the zoo they were housed separately at an average temperature of 23° C. Skylights provided a natural photoperiod.

The snakes were moved to a hibernation chamber on 10 November 1981. The temperature in this room fluctuated with outdoor temperatures, but averaged 9° C (range 5°-16° C). While in hibernation, the glass fronted cages faced large windows with an eastern exposure. After 83 days in hibernation (2 Feb 1982), both snakes were returned to a warm environment (19°-23° C).

On 25 February 1982, the snakes were placed together in an all glass aquarium (L-73, W-31, H-28 cm). This cage was fitted with a 15 watt fluorescent light fixture attached to the wooden top. The light was controlled by an automatic and self-adjusting natural photoperiod duplicating device (Llewellyn 1972). The sides of the aquarium were covered with paper to minimize the influence of other building lights, and also to eliminate the potential disturbances caused by keepers working in the area. Gravel was used as a substrate. The snakes consumed both live and pre-killed rats and mice on a weekly basis.

Courtship behavior by the male was first observed on 26 February 1982, and continued intermittently through 28 February, but the female was unreceptive. Courtship recommenced on 8 March, but the female remained unreceptive. She often retreated into one of the hide boxes provided. Finally on 13 March, copulation was witnessed several times between 1400 and 1530 h. During copulation the pair was very calm. They were undisturbed when the cage lid was lifted for photographic purposes. Further copulation attempts were not witnessed.

The female fed twice after copulation, the last time on 1 April. A plastic container, partially filled with damp vermiculite was placed

in the cage to provide a suitable site for oviposition. Seven eggs were laid in a damp corner of the cage on 28 April 1982. The container holding vermiculite was totally ignored. Wright and Wright (1957) mention a captive breeding of *deserticola* in which the gestation was 49 days, compared to the 41 day period observed in the present study.

The adherent eggs had a mass of 196 gms. All eggs were of similar size and shape (ca. 6 cm in length by 2.5 cm in diameter). Accessible surfaces of the clutch were wiped clean with zephiran chloride (1:750 solution). The clutch was covered with damp vermiculite, and placed in a closed (not airtight) stainless steel container. A still-air poultry incubator set at 29.5° C was used for incubation.

The first egg slit after 55 days of incubation, and by day 58 all seven eggs had hatched. The hatchlings were weighed ($\bar{X}$ = 19.8, range = 17.8-22.4 g), and measured to the nearest mm by gentle stretching (SVL $\bar{X}$ = 34.7, range = 32.2-35.9 cm; TL $\bar{X}$ = 40.2, range = 38.0-41.6 cm). The young snakes appeared to be in excellent condition. A large amount of yolk was visible through the ventral skin of each snake. Fifteen days after hatching all had completed their first shed, and the hatchlings fed readily on newborn mice soon afterward.

Fitch (1970) describes *Pituophis* as spring breeders with early summer oviposition, and autumn hatching. This captive breeding fits that pattern fairly well. The results of this study indicate that a lengthy (i.e. natural) hibernation period is unnecessary for successful captive propagation of *Pituophis melanoleucus deserticola*.

ACKNOWLEDGMENTS

I would like to thank the staff of the Cheyenne Mountain Zoological Park for their support, and Janet Boggs for typing the manuscript. This study was supported by a grant from the Society for the Study of Amphibians and Reptiles.

A CAPTIVE BREEDING OF THE AUSTRALIAN DEATH ADDER, *Acanthophis antarcticus*

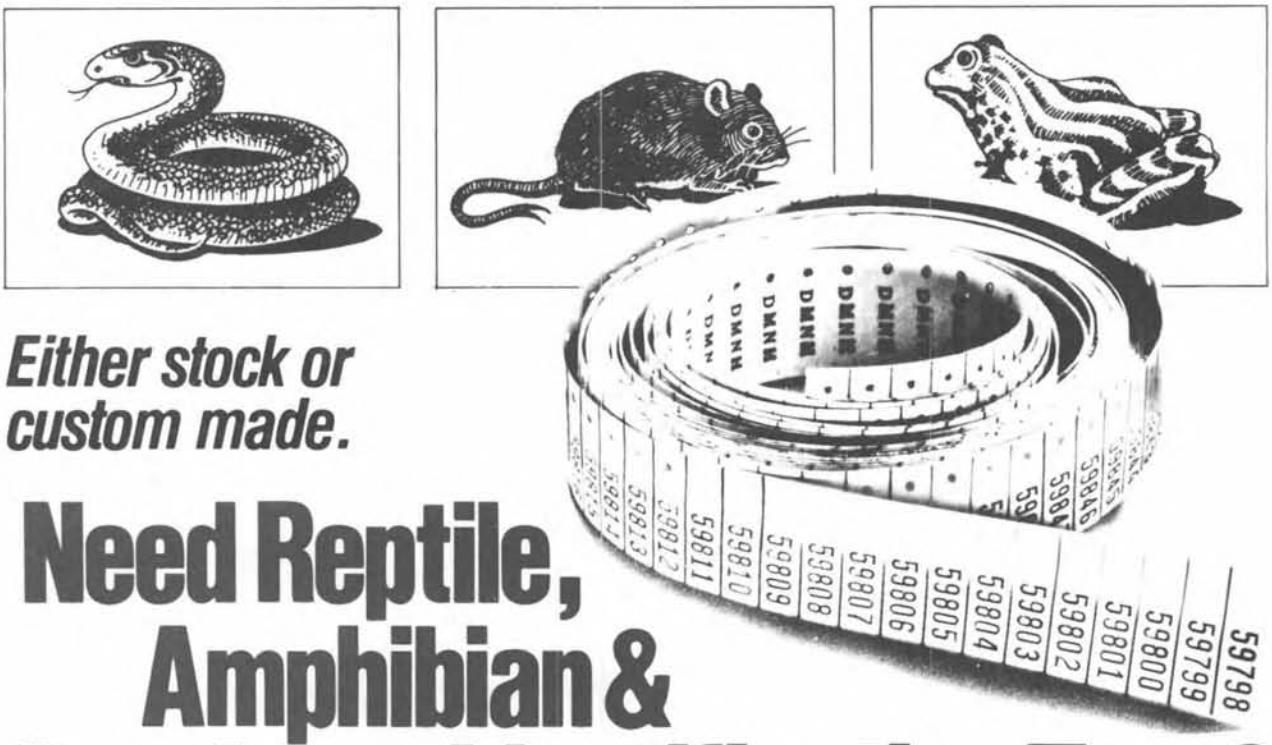
Death adders are popular zoo exhibits but reports of captive breeding are rare (Hay 1972; Hudson 1979; Mirtschin 1976, 1982). We report the captive propagation of 12 litters of death adders over a seven year period. The parents of at least six of the litters had been conceived and born in captivity.

MATERIAL AND METHODS

The origins of the parents and the first successful breeding have been reported elsewhere (Hay 1972). Briefly, the female was 29 cm (all measurements in this paper are of total length) when captured in January 1964. The male was 57 cm when captured in November 1966. Copulation was observed January-March and October-November 1968 and October-December 1969. No copulation was observed in 1970 and the first brood was produced 11 March 1971. The female was 77.5 cm and the male 66.0 cm in December 1970. They were maintained in a 60 X 60 cm glass aquarium with leaf litter and gravel on the floor.

The death adders were kept in various aquariums, ranging from 60 X 30 cm to 150 X 45 cm from then until 1978. They were exposed to the natural photoperiod of Sydney, Australia, and the temperature regime was natural except for the slight "glasshouse" effect of the shed in which the aquariums were maintained. All of the first litter and representatives of subsequent litters were maintained in 60 X 30 cm glass aquariums with gravel and leaf litter on the floors under natural photoperiod and without artificial heat.

RESULTS AND DISCUSSION



A second litter was produced 10 March 1972. The original male died before the production of the second litter and the female had no opportunity to mate until 7 November 1971 when another male was introduced into the cage. The male repeatedly attempted to copulate but was ignored by the female until he gave up and coiled under the leaves. He was removed from the cage 10 November 1971 when inspection of the female indicated that she was already gravid. Although it cannot be proven that copulation did not occur in 1971 these observations suggest that insemination was by the original male and that the female stored sperm (see also Hay 1972). A third litter was produced 4 March 1973, but no litters were produced in 1974.

By 1 June 1973 females of the first brood were considerably larger ($\bar{X}$ = 324 g, range = 271.4-367.6 g) than the males ($\bar{X}$ = 239 g, range = 174.5-332 g) despite having had access to similar quantities of food. On 20 November 1973, three males of the first litter were observed copulating with their sisters (same litter). They were then 32 months old, about one year older than the age at sexual maturity predicted by Shine (1980) from sizes of specimens in museum collections, and also about one year older than males when they first mated in captivity under constant temperature (29° C) conditions (Mirtschin 1982). Females of that litter did not produce young until March 1975 when they were 48 months old. This agrees with Shine's (1980) estimate of 42 months at first ovulation for death adders in the wild. Progeny of the original female after 1975 were sired by one of her sons (unless, more doubtfully, she was using stored sperm).

From 1975 on records were less precise. Dates of parturition, clutch sizes and sex ratios at birth for all broods are summarized in Table 1. Parturition always occurred in March, but the timing varied between years. The first three litters of the original female (1971-1973) were produced between 4 and 10 March. The five litters in 1975, including that of the original female were produced between 24 and 29 March. Litters in 1976 were produced between 5 and 11 March. It appears that parturition is relatively synchronous among captive females but that the stimulus producing synchrony varies between years. In the wild, female death adders apparently breed only in alternate years (Shine 1980). Shine presented three hypotheses regarding the selective pressures that lead to biannual reproduction, two of which related to mortality rates, and one to food availability. As at least one of the death adders reported here reproduced in three consecutive years, it appears that death adders can respond to the

extra food available in captivity and that the reproductive interval is not fixed genetically.

The sex ratios of seven of eight litters that were sexed at birth were slightly skewed towards females. This result is significantly different from random ($\chi^2 = 4.5$, $p < 0.05$). However, it may not reflect a population characteristic as at least four of the litters were from one female and the rest were from her progeny. In any case, the overall bias towards females (55%) was slight.

Clutch size was fairly constant among and within females, and the data from the original female offer little evidence of a large increase in clutch size with age, consistent with the lack of correlation between clutch size and female size in wild death adders (Shine 1980).

The mean ($\pm$ SD) masses and lengths of young produced in 1972 and and 1973 were 6.69 ± 0.42 g, 16.6 ± 1.2 cm and 8.65 ± 0.62 g, 15.6 ± 0.33 cm, respectively. Lengths and masses were not determined for other litters. The young did not eat until they sloughed their skins 14-17 days after birth. During that time the second litter lost 3.8-16.7% ($\overline{X}$ = 11.3%) of their mass, but increased 6.3-14.4% ($\overline{X}$ = 9.7%) in length. Neither adults nor juveniles ate during the Sydney winter. Weight loss of a sample of eight juveniles from the first litter during their first brumation (1 June-1 September) was 7.7 ± 2.3%.

The death adders were fed lizards, small birds and mice. The snakes readily took lizards, but one species, *Ctenotus taeniolatus*, from the Sydney region may not be a suitable food. Two juveniles from the first litter died in 1972 and were infested with pentastome lung worms. Those snakes had been fed only *C. taeniolatus* since birth. Another snake died in 1973 of the same cause. A single *C. taeniolatus*, recently captured from the wild, which showed similar symptoms (spasms and mouth gaping apparently associated with attempts to dislodge worms from the trachea) had a large pentastome in its lung. Apparently, *C. taeniolatus* can act both as a primary and as an intermediate host for the pentastomes. Giving only other species of lizards when the death adders were small, and feeding them only on mice when larger, avoided further problems with pentastomes.

ACKNOWLEDGMENTS

John Cann lent his death adder for breeding trials in 1972. Harold Cogger and Gerry Swan provided copies of articles in regional journals. Leonete Pacheco typed the manuscript.

TECHNIQUES

"TAPPING": A TECHNIQUE FOR CAPTURING TORTOISES

Capturing and recapturing tortoises without excavating or disturbing the burrow system has been considered important. Woodbury and Hardy (1948) describe using a half-inch metal pipe with a hook to pull desert tortoises from their burrows. Carpenter (1955) used sticks and blunt rods made of aluminum tubing to locate turtles under leaves, debris, or soil by sounding. Carpenter stated that a stick striking the carapace made a hollow sound easily distinguishable from that of a piece of wood or stone. R. C. Stebbins (pers. comm.) stated that naturalists have used the tapping technique to get desert tortoises out of burrows. One of us (Medica) first tried tapping in Coahuila, Mexico, in June 1959. Using a flashlight, he observed a Texas tortoise *(Gopherus berlandieri)* about 2 m within a burrow under a large boulder. He tapped on the carapace of the tortoise with a 2 m bamboo pole to see if the tortoise would move. Within a few minutes, two tortoises (male and female) emerged from the burrow.

We have used the tapping technique with desert tortoises *(Gopherus agassizii)* since 1967 in southern Nevada and in southeastern California. In Ivanpah Valley, San Bernardino Co., California, we recaptured and weighed tortoises with radiotransmitters regularly during 1980 and 1981 (Turner et al. 1984). The tapping technique enhanced this effort significantly. Of 440 captures and recaptures of tortoises in Ivanpah Valley in 1980, 103 (23%) were the result of successfully tapping and capturing animals in burrows. Of 1,111 captures and recaptures in 1981, 219 (19.7%) were recaptured by tapping.

A tortoise deep in its burrow should be tapped 3-4 times on the carapace with a stick (we used surveyor's laths). The observer should then remove the stick and move away from the burrow entrance. If the burrow is too deep (or turns) and the tortoise cannot be tapped directly, striking the roof or the floor of the burrow, or pounding on the mound at the entrance to the burrow may produce results. If the tapping is successful the tortoise will turn in its burrow and emerge rapidly, usually to the burrow entrance. If tapping does not result in an immediate reac-

tion, it should be repeated several times. Unless movement is heard from within the burrow within a few minutes, further tapping is fruitless. The above procedure is particularly useful after normal aboveground activity of tortoises has ceased (ca. 0930 h in June and 0830-0900 h in July).

Male and female tortoises responded similarly to tapping. During two seasons in Ivanpah Valley, 119 of 144 males tapped (82.6%) and 203 of 249 females (81.5%) emerged from burrows. Chi-squared totals computed for 1980, 1981 and both years combined were statistically insignificant. Response increased as the season progressed and the weather became warmer and drier (Table 1). The significant seasonal effect may have been associated with higher tortoise body temperatures. Tortoises with high body temperatures may respond more readily to stimulation. Chi-squared tests showed that tortoises were significantly more responsive to tapping in 1981 than in 1980. March-April results were from 1981 only, and 1981 was the year in which tortoises were apparently more prone to emerge. Hence, there is an apparent reluctance to emerge early in the season.

Many tortoises were tapped and captured more than once (Table 2). The χ^2 0.05 value (with 3 d.f.) is 7.82 indicating a significant difference in emergence due to frequency of tapping.

Why do tortoises react to tapping and emerge from burrows? Emergence may be an aggressive response to presumed interference by another tortoise. The response may be associated with courtship or mating behavior (e.g., see Harless 1979). The more frequent response in 1981 and the data in Table 2 suggest that some type of conditioning may result from tapping. However, no "reward" was ever given to captured individuals. Tortoises were simply weighed, measured, and released at burrow entrances.

Tapping is a simple, practical method of increasing the number of captures and recaptures of desert tortoises. The technique may also be successful with other burrow-inhabiting tortoises.

A TECHNIQUE FOR MARKING TEIID LIZARDS IN THE FIELD

Marking with unique colors and patterns of paint is a commonly used field technique for identifying lizards (Ferner 1979). This technique is not practical for field studies of teiid lizards because the paint tends to come off in a short time (1 to 5 days; Carpenter 1959). This is partly because it does not adhere well to a teiid lizard's small dorsal scales and partly because teiids often live in sandy areas where activities such as burrowing cause the paint to flake off. I have developed a technique for marking teiid lizards by gluing colored plastic bird bands to their tails. This technique was tested during a field study of the six-lined racerunner, *Cnemidophorus sexlineatus*, in Oklahoma.

Plastic leg bands were obtained from National Band and Tag Co., Newport, Kentucky, U.S.A. I used size 3 coiled leg bands (internal diameter 3/16 in) for *C. sexlineatus*. The bands were cut so only a single complete ring was used with no gap between the ends. Bands were rolled betwen the thumb and forefinger to reduce the diameter for use on small lizards (sometimes I also cut the width of the band in half with scissors). The band was slid up the tail until its leading edge was just tight against the skin and glued in place with two drops of Duro® superglue applied to the inside of the distal end of the band. It is best to glue the band about two-thirds of the way up the tail, which reduces the possibility of losing the band by autotomy and does not interfere with leg movement, defecation, or copulation. Two or three bands may be used on one lizard allowing a large number of unique color combinations. If multiple bands are used, it is best to leave a space between bands so the tail can move freely.

Plastic bands are no encumbrance to adult racerunners and do not alter normal behavior. However juveniles may be hindered by their bands when they climb into small bushes especially if more than one band is used (I never used more than two bands on lizards with a SVL of less than 40 mm). The bands are typically lost when the skin is shed, however if the lizard is growing rapidly, the diameter of the tail distal to the band may increase so the band can not come off. In this case, the band is essentially permanent although the tail becomes constricted at the band. In extreme cases the old band should be removed and a new band put on to prevent severe deformity. Based on records of banded lizards I have resighted more than once, average "band life" is 26.4 ± 14.1 days (range 4 to 63 days, N=23).

I found this technique to be a convenient way to identify individual racerunners in the field. It allowed observation of movements, activity cycles, and behaviors of individuals over several weeks without subjecting lizards (and investigators) to the stress of repeated captures. In combination with standard toe-clipping, this technique can be a useful tool in field studies.

I wish to acknowledge Charles C. Carpenter, James J. Krupa, and Robin K. Richardson for reviewing this note and Michael A. Mares for suggesting this technique.

IMPLANTING LONG-RANGE TRANSMITTERS IN PRAIRIE RATTLESNAKES, *Crotalus v. viridis*

External attachment of radio transmission equipment obviously is not possible on snakes. Most researchers using telemetry (e.g. Osgood 1970; Fitch and Shirer 1971; Parker and Brown 1972; Kroll et al. 1973; Jacob and Painter 1980; Sanders and Jacob 1981) have force-fed transmitters to snakes, a procedure which often results in short tracking periods due to regurgitation of the transmitter. Speake et al. (1979) tested several designs for transmitters and implantation techniques in indigo snakes, *Drymarchon corais*. Brown and Parker (1976) and Reinert and Cundall (1982) described surgical techniques for the intraperitoneal implantation of transmitters with external loop and whip antennae respectively. Weatherhead and Anderka (1984) implanted transmitters and antennae subcutaneously. In this paper, I present the procedures utilized and results obtained from surgically implanting new, long-range, commercially available transmitters into peritoneal cavities of prairie rattlesnakes *(Crotalus v. viridis)*. The encapsulation procedures used here greatly reduced the degree of permeability, and the anaesthetic, ketamine HCl, was easily and quickly administered, making it safer for the investigator and the snake.

VHF transmitters (Model KG80, Austec Electronics Ltd., Edmonton, Alberta, Canada), pulsed by a CMOS with a Fenwall GA62JI (2 MEG) thermistor (paralleled with 3.9 MEG resistor), were powered by TADIRAN 3.4 V high energy lithium batteries, TL-2100 (size AA). The life of the transmitters was at least 400 days at 23 C° (one pulse every .66 sec.), with a range of approximately 1.6 km (direct line of sight). Frequencies were in the 150.800-151.375 MHz range and pulse rates were positively correlated with body temperature. Actual body temperatures were calculated from pre-determined calibration curves: pulse interval (sec) vs temperature (ranging from 40° to -40° C). Pulse rates were accurate to 0.3° C. The receiving equipment used consisted of an AVM portable receiver (Model LA 12, AVM Instrument Co., Illinois) and an RA-3A hand-held antenna (Telonics Inc., Mesa, Arizona).

The first transmitter measured 16.5 cm in total length (9 cm was teflon coated, solid stainless steel whip antenna), 1.4 cm in diameter and had a mass of 21 g. The transmitter was encapsulated in 0.6 cm thick silicone cementing compound (Dow-Corning 3145) and had a mass of 30.5 g.

Eighty-eight milligrams (88 mg) of ketamine HCl were injected intramuscularly into the tail of the first rattlesnake with a mass of 618 g (142 mg/kg). Wallach and Boever (1983) reported that 66-88 mg ketamine HCl are required for major surgery, and doses greater than 132 mg/kg body mass required respiratory support. Complete immobilization (the rattlesnake could not right itself when laid on its back) took 5 min. The transmitter was sterilized in antiseptic and inserted through a ventral 3 cm transverse incision (the width of the snake's ventral surface) between the ventral scutes, 19 cm anterior to the cloaca. The whip antenna pointed posteriorly and ran parallel to the intestinal tract. The body cavity was flushed with 10^6 IU (3 cc) of penicillin squirted into the body cavity and the incision was closed using 7 self-absorbing sutures. The operation took a total of 42 min and no respiratory support was needed. Full recovery (rattlesnake alert and rattling with normal movement) took 3 h 20 min.

The transmitter stopped transmitting 3 days after implantation. X-rays showed that the transmitter shifted anteriorly 2 cm, and the whip antenna was being severely bent, allowing body fluids to penetrate the protective silicone cementing compound and short-out the battery. Donaldson (1980) discusses problems associated with encapsulation and packaging implanted components.

Subsequent transmitters differed from the first by using teflon coated (18.2 kg (40 lb) test), stainless steel fishing leader antenna encircling (or looping) the battery. Each of 5 transmitters was individually sealed inside a pre-formed dental acrylic capsule. The capsule was made in two half sections, sealed together with a quick-drying resin and hardened under a pressure of 9070 g/6.5 cm (20 psi) and a temperature of 30° C while immersed in a water bath in a pressure cooker. It was imperative that the dental acrylic harden under pressure and high temperature while immersed in a water bath. This removed any air bubbles which may have formed in the acrylic as it was mixed. Although dental acrylic is permeable over long periods, permeability is greatly reduced when this procedure is used. To prevent internal movement of subsequent transmitters, a small stainless steel loop was affixed with acrylic to the capsule and the capsule was "rounded off" using a fine electric grinding stone. The average thickness of the acrylic was 0.7 mm. Each transmitter measured 5.7 cm in total length, 2 cm in width and averaged 27 g mass. Encapsulation averaged 1 hr 10 min per transmitter.

The rattlesnake implanted with the first transmitter was anaesthetized after 8 days using the previous dose of ketamine HCl. The non-functional transmitter was removed through a second incision made 2 cm anterior to the first (which had healed well). A non-dissolving suture was threaded through the small stainless steel loop and sewn to the musculature of the body wall at the place of incision. The operation took 36 min and full recovery time was 1 hr 50 min. This animal was released 4 days later at the site of capture. The incision healed extremely well after one week and no apparent problems were encountered with ecdysis.

Four additional rattlesnakes (ranging in mass from 441-609 g) were anaesthetized with 40 mg ketamine HCl (a smaller dose was used to shorten recovery times). Insertion, internal suturing and flushing the body cavities were carried out as described above. Each operation was completed within 25 min at which time the snakes attempted to right themselves. Each snake started crawling within 48 min and was alert and rattling within 55 min. Five days after implanting, the rattlesnakes were released at the sites of capture.

In all four snakes the incisions healed completely after one week. There were no apparent problems with ecdysis. Four transmitters functioned for more than 400 days (range 431-472) without problems (after 400 days pulse rate accuracy deteriorates). One transmitter functioned without problems for 288 days but was then lost. Golden eagles *(Aquila chrysaetos)*, great-horned owls *(Bubo v. virginianus)* and red-tailed hawks *(Buteo jamaicensis)* frequented the study area and may have carried the snake beyond the receiver's range. Predation by badgers *(Taxidea taxus)* may also have destroyed the transmitter.

Prairie rattlesnakes can overwinter at great depths and up to 8 months in temperate climates. For these extended studies it was necessary that the transmitters be powered by large batteries: transmission range and longevity can only be increased by increasing battery size (and thus the bulk of the transmitter package). Weatherhead and Anderka (1984) used small Lithium-Thionyl Chloride batteries (290 mAh capacities at 3.5 V) to power their transmitters, with a longevity of 423 days, but maximum transmission range was 150-300 m.

The transmitter system described here greatly reduces time spent searching for snakes in the field, particularly in rough or hilly terrain. Although full, transverse incisions for implantation may appear drastic, no adverse effects on the snakes were evident since all recovered quickly and resumed normal movement. Although the size of the transmitter package restricts its use in thin-bodied snakes, the transmitters can be powered by smaller batteries.

Austec Electronics Ltd. supplies and services radio transmission equipment outside Canada (presently New Zealand, Australia, England, and the United States). Because of patent rights, the transmitter circuit board was not described in this paper.

ACKNOWLEDGMENTS

I am grateful to Mr. Keith Brockelsby, Austec Electronics Ltd., Edmonton, Alberta for sharing his ingenuity and expertise in electronics, and to Dr. Jim Carney for his interest and assistance in the implantation of the transmitters. I also thank Mr. Bob Stewart for his patience and design of the transmitter capsules.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, U.S.A.

NEW ZEALAND
AMPHIBIANS
AND
REPTILES
IN COLOUR
JOAN ROBB

NEW ZEALAND AMPHIBIANS AND REPTILES IN COLOUR presents an informed account of the amphibians and reptiles of New Zealand, both native and introduced. It gives detailed descriptions of all of their frogs and lizards, and New Zealand's most ancient creature, the tuatara. The text is accompanied by 145 color photographs, 12 black & white photos, 14 drawings, 43 range maps, diagrams, a glossary, notes on scientific names and section on diseases and parasites. This softbound edition is revised from the 1980 edition with 3 newly described forms of lizards and all the information is updated in the light of current research. 128 pages. Softcover 7½ by 10 inches.

THIRD REVISED AND ENLARGED EDITION (1983)

By H.G.COGGER I.S.B.N. 0 88359 012 3

In this book Dr. Cogger has set out to provide for the first time in nearly a century, identification keys to the entire Australian herpetofauna - frogs, crocodiles turtles, lizards and snakes. These keys, together with over 880 photographs (230 in color) of living reptiles and frogs, 830 distribution maps, line drawings, definitive text and selected references, combine to provide a unique and comprehensive guide to this important and facinating animals.

This third edition of what has, since first pubilication in 1975, become a classic in its field has been revised and expanded to encompass the taxonomic changes which have occurred since publication of the second edition in 1979. A further 121 species have been included together with 64 additional photographs and all photographs have now been fully cross-referenced to the text.

ANURA

ASCAPHUS TRUEI (Tailed Frog). **BEHAVIOR.** Nussbaum et al. (1983. Univ. Press, Idaho) indicate that *A. truei* occur in close proximity to fast-flowing, permanent streams, occasionally venturing into nearby woods following rains. Bury and Corn (pers. com., Denver Wildlife Research Center, USFWS) have evidence that juvenile frogs in a western Washington population leave the stream after metamorphosis and move overland.

On the morning of 22 May 1984 an adult female (50 mm TL) was found under bark on a downed, partially decomposed, Tan Oak log *(Lithocarpus densiflora)*, 40 m from the nearest stream. The frog was 15 cm above ground. The air temperature was 10° C, and there had been no rainfall in the area since 15 May. The site was at 1350 m near Brush Creek in the Illinois River drainage of southwestern Oregon (T40S, R7E, Sec. 23). The specimen is deposited at the Redwood Sciences Laboratory (RSL 21093). Contribution No. 32 of the Old-growth Forest Wildlife Habitats Program, USDA Forest Service.

Submitted by **HARTWELL H. WELSH, JR.** and **RICHARD J. REYNOLDS,** Redwood Sciences Laboratory, Pacific Southwest Forest and Range Experiment Station, USDA Forest Service, 1700 Bayview Drive, Arcata, California, U.S.A. ●

CAUDATA

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). **FEEDING.** On 25 September 1982 a female *Ambystoma t. tigrinum*, (79.5 mm SVL, 20.8 mm head width) was collected in a limestone quarry in southwestern Iowa. This specimen contained a hatchling *Cnemidophorus sexlineatus viridis* in its stomach. The lizard was swallowed tail first and the tail was bent anteriorly at its base. The bolus, made up of only the lizard, measured 32.3 mm in length by 12.0 mm wide.

The salamander was found in a shallow hole near several small gravel piles where young and adult *Cnemidophorus* were observed. It was speculated that the salamander captured the lizard underground while the lizard was inactive.

Few reports of metamorphosed *A. tigrinum* feeding on vertebrates exist. Ditmars (1905 Amer. Mus. Jour. 5:161-208, figs. 1-28) reported that adults ate young field mice and Hay (1892. The Reptiles and Batrachians of the State of Indiana. 17th Ann. Report Geol. and Nat. Res., Ind. pp. 409-602, pls. 1-3.) reported that captive adults ate *Acris* and *Hyla versicolor*. I observed captive adult *A. tigrinum* from Illinois feeding on an adult *Storeria dekayi* and attempting to swallow an adult *Rana sylvatica*.

This note further documents the opportunistic feeding habits of *A. tigrinum*. *Cnemidophorus* are probably infrequent in the diet of *A. tigrinum*.

I thank J. L. Christiansen and J. R. Dixon for reviewing and commenting on the manuscript. The specimen (JDC-5) and stomach contents were deposited in the Drake University Research Collection.

Submitted by **JEFFREY D. CAMPER,** Department of Biology, Drake University, Des Moines, Iowa 50311, U.S.A.

Present address: Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, U.S.A. ●

DICAMPTODON ENSATUS (Pacific Giant Salamander). **BEHAVIOR.** Documented habitat affinities for neotenic *D. ensatus* indicate a strictly aquatic usage (Nussbaum et al. 1983. Univ. Press, Idaho; Stebbins 1966. Houghton Mifflin Co.). On 19 November 1984, a neotenic male, 221 mm TL, 7 mm gill length, was captured in a pitfall trap 3 m from a small stream. The terrestrial habitat between the stream and the trap consisted of moss covered ground and a dense cover of low (0.2 m), shrubby vegetation, predominantly *Berberis nervosa*, Forest Barberry. The area had received five days of intermittent rainfall between trap checks; both the ground and the vegetation were wet, and the trap had collected 2 cm of water. The site was in old growth Douglas Fir forest in the Butte Creek drainage at 1070 m, Humboldt Co., California. The specimen is deposited at the Redwood Sciences Laboratory (RSL 1022). Contribution No. 31 of the Old-growth Forest Wildlife Habitats Program, USDA Forest Service.

Submitted by **HARTWELL H. WELSH, JR.,** Redwood Sciences Laboratory, Pacific Southwest Forest and Range Experiment Station, USDA Forest Service, 1700 Bayview Drive, Arcata, California 95521, U.S.A. ●

SAURIA

BASILISCUS PLUMIFRONS (Crested Green Basilisk Lizard). **FOOD.** Hirth (1962. Herpetologica 18(4):276-277) reported food items of *Basiliscus plumifrons*, from Costa Rica, included vegetation, insects, crustaceans (shrimp and crabs), and a mammal (a free-tailed bat).

On 8 August 1980, a young adult male *Basiliscus plumifrons* (ca. 70 cm TL) was captured soon after nightfall ca. 6 km N.E. of Bri Bri, Limon province, Costa Rica. The lizard was captured while sleeping on vegetation overhanging a small hillside stream of the Rio Sixaola drainage. While biting the hand of its captor, the hind legs of a frog were observed in the lizard's throat. The frog was removed and identified as an adult *Rana warschewitschii* (ca. 5 cm TL). The frog appeared to have been recently ingested as very minimal digestion had occurred. Unfortunately, neither specimen could be preserved due to lack of preservation equipment.

Although frogs have not previously been reported in the diet of *Basiliscus plumifrons*, Barden (1943. Copeia 2:118-121) reported frogs (species not identified) in the diet of *Basiliscus basiliscus* in Panama.

BIOLOGY of AUSTRALASIAN

Frogs & Reptiles

Edited by
G. Grigg, R. Shine and H. Ehmann

Reviews and Research on the
ECOLOGY, BEHAVIOUR, PHYSIOLOGY, BIOGEOGRAPHY, CONSERVATION, EVOLUTION and REPRODUCTION
of Australian and New Zealand Reptiles and Frogs

This book is the first major review of the Biology of Australasian Frogs and Reptiles. The Australasian herpetofauna is colourful, diverse and spectacular, and has recently attracted considerable attention from research scientists. The framework is not taxonomic but biological, ranging from reproductive behaviour to evolution, from population biology to captive breeding and husbandry, from zoogeography to the conservation of rare and endangered species.

Available from N. Fagin Books Ill., Wildlife Services Col., Wildlife Publication Flor., Herpetological Book N.Y., K. Neitman Tex., Donald E. Hahn Ariz., Avocet Books N.C. or direct from Publishers.

GERRHONOTUS KINGI (Arizona Alligator Lizard) **REPRODUCTION.** On 11 October 1982, at 1304 h, I introduced a recently captured male *G. kingi* (8.9 g; 85 mm SVL) into a 310 l plexiglass terrarium (1.52 m X 0.46 m X 0.46 m) with a shallow bottom of fine gravel and scattered leaf litter. Four conspecifics were already present. The male moved slowly over the substrate, extruded his tongue approximately once every 2-3 sec, and exhibited a *slow* side-to-side head motion. After several minutes a large female (31.0 g; 109 mm SVL) moved in the litter. The male immediately oriented toward the female (a distance of approximately 50 cm). As the female continued to move, the male approached to within 30 cm, halted momentarily, vibrated the posterior third of his tail, and continued his approach with a *rapid* side-to-side head motion. (While no exact time measurement was recorded for the side-to-side head motions, the difference in cadence between the first movement and the second was easily discernible.) Head movement, in the pattern of a flattened ellipse, appeared to be clockwise for several revolutions and then counterclockwise for a similar period. Tongue flicking continued throughout these preliminary movements by the male and occasionally by the female.

When within 5 cm, the male oriented toward the female's vent, tilted his head down at a 40-60° angle from the horizontal, and arched his body. The female, in response, tilted her head down at a 30-40° angle and pulled her body slightly away from the male in an S-shaped figure. The male moved toward the female's nape, opened his mouth, and gripped one-half of her neck region. The male slowly worked his tail under the female's tail, elevating her vent region. After several seconds, vent alignment was achieved. The copulatory position (Figure 1) was held intermittently for the next 32-43 h. Intromission could not be seen, but is assumed to have occurred.

Intervals between pulse times (the male pushing his vent against the female's vent in a rhythmic fashion for 2-3 sec periods) were erratic. Mean interval between pulses was 9 minutes (coefficient of variation = 40%). During the 25 hours of observations (1304, 11 Oct. to 0500, 12 Oct.; 0952-1330, 1540-2100, 12 Oct.), lizards were in the vent alignment position for 12.4 hours. The remainder of the time the male struggled to maintain his grip on the moving female or they sat motionless. Vent alignment was broken by the female at least 12 times and total displacement from the site of first copulation was 1.4 m. I believe holding and copulation continued for the 43 hour period because the female was found (at 0800, 13 Oct.; 43 hour mark) in the same position and area of the terrarium as when last observed (2100, 12 Oct.; 32 hour mark).

On 18 October, at 1313 h, the pair was again observed copulating. This mating sequence lasted until 0745 (19 Oct.), but was interrupted so that intromission could be confirmed.

Length of mating time may be an artifact of conditions under which it was observed. However, other anecdotal information supports long mating times in the gerrhonotine lizards. Stebbins (1959. Reptiles and Amphibians of the San Francisco Bay Region, University of California Press, Berkeley and Los Angeles, California.) suggested a mating time of 24 h and similar copulatory position for *G. multicarinatus*, while Fitch (1935. Trans. Acad. Sci. St. Louis 29:1-38) observed mating in *G. coeruleus* for 4¾ hours. Smith (1946. Handbook of Lizards, Comstock Publishing Associates. Ithaca, New York) suggested that mating may take from 12 to 26 hours for *G. multicarinatus*. Long copulatory periods seem characteristic of the genus.

Figure 1. Copulatory position of *Gerrhonotus kingi*.

I thank J. Fouquette, B. Sullivan, and E. Bowker for their editorial comments. I also appreciate observations made in my absence by E. Bowker and B. Sullivan and loan of a mature female *G. kingi* by C. Levy.

Submitted by **ROBERT W. BOWKER,** Arizona State University, Tempe, Arizona 85287, U.S.A. ●

SERPENTES

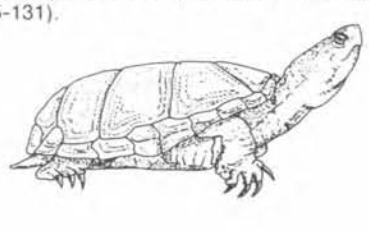
BUNGARUS FASCIATUS (Banded Krait). **REPRODUCTION.** A female *Bungarus fasciatus* was received at the Sedgwick County Zoo on 5 April 1985 from a commercial dealer. The specimen did not appear to be gravid at that time.

This individual was introduced to a long-term captive male on 19 May 1985 for a breeding attempt. The female was removed from contact with the male the following day, after brief courtship behavior by the male was observed. No further breeding efforts were made.

On 20 June 1985 a clutch of seven adherent eggs was found in the female's holding unit. The eggs were somewhat desiccated and had probably been laid the previous day. The clutch was placed in a one gallon glass jar and completely covered with moist vermiculite (water to vermiculite ratio 3:1 by weight). The jar was sealed with plastic sandwich wrapping and placed in an incubator. The clutch had a mass of 127.2 g ($\bar{X}$ = 18.1 g). The eggs ranged in length from 49-59 mm, ($\bar{X}$ = 53 mm), and were thin-shelled, smooth, and somewhat banded with oblique vermiculations.

On 3 August 1985, all eggs hatched after a 44 day incubation period with an average temperature of 84.5° F (range 81°-93° F). Masses for the neonates were 11.4 g-17.3 g ($\bar{X}$ = 14.8 g). The young appeared to be physically normal, except for pattern anomalies in two individuals. One neonate was marked with paired lateral blotches rather than bands. The other individual was partially banded, partially blotched. The young differed from the parents in that the ground color was pale lavender rather than yellow.

We believe this event to be the second captive hatching of this species in the United States. It is possible that it is the result of a captive breeding but, given an unusually short incubation period and what would have been an unusually short gestation period, we feel a wild breeding is more likely.



The pattern anomalies in the two neonates can probably be explained by two factors: an incubator malfunction wherein incubation temperatures reached 93° F for 14 h, and desiccation of the eggs at laying. The female parent showed no signs of abnormal patterning.

In contrast to previous reports, the female showed no sign of brooding or egg-guarding behavior.

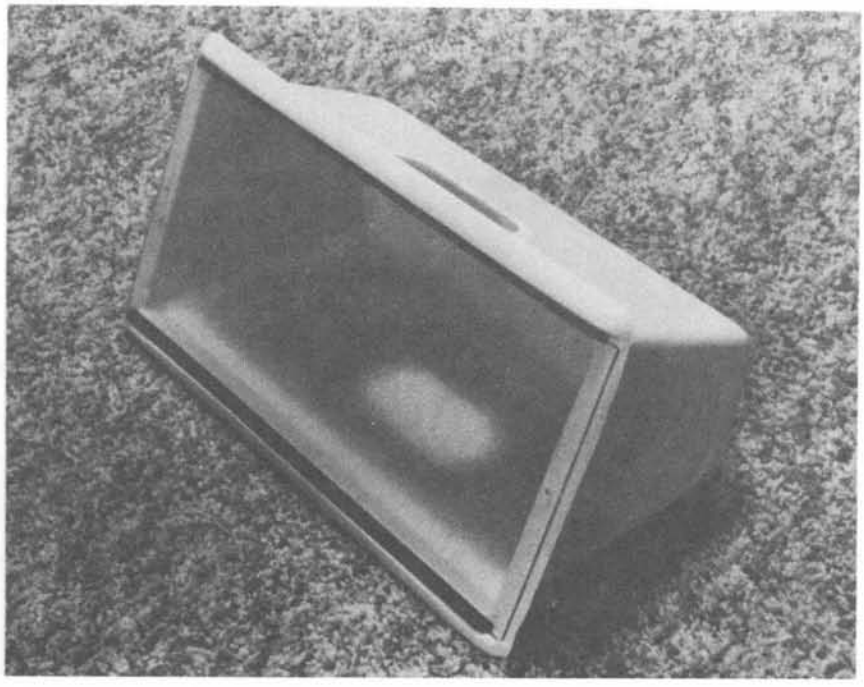
Sedgwick County Zoo
Wichita, Kansas 67204, U.S.A. ●



CROTALUS ATROX (Western Diamondback Rattlesnake). **PATTERN.** A gravid *Crotalus ktrox* (total length = 800 mm; postpartum mass = 205 g) with normal pattern and coloration was collected 18 July 1984, about 8 road miles south of Stanfield, Pinal Co., Arizona. Sometime between 28 September and 1 October 1984 this snake produced seven young, all with aberrant patterns but normal coloration. Three offspring appeared healthy, but four were either stillborn or crushed, and partially decayed. Surviving young lived for two, six, and 11 weeks respectively; one offspring never fed while two fed poorly on dead baby mice. Two of these offspring are in the reptile collection of the Department of Zoology, Arizona State University (# 23481, 23482).

All seven young showed abnormal longitudinal striping in the caudal and precaudal regions. Five showed striping in the neck region, and four showed merging of dorsal blotches midbody (Fig. 1). One young showed reduced scalation in the interorbital region. An adult *C. atrox* (length = 750 mm) with similar aberrations was reported from the Tucson Mountains, Pima Co., Arizona, about 60 air miles SE of the present locality (Nickerson and Mays 1968. Wasmann J. Biol. 26(1): 125-131).

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

NP NEODESHA PLASTICS INC

TWIN RIVERS INDUSTRIAL PARK
P O BOX 371 – NEODESHA KS 66757
A/C 316 325-3096

Figure 1. Aberrant *Crotalus atrox* with striped pattern.

Striping is common among aberrations reported in crotalid snakes, and is often attributed to recessive genetic traits (Antonio and Barker 1983. Herp. Review 14(4):108-110; Bechtel 1978. J. Herp., 12(4):521-532); Gloyd 1935. Pap. Mich. Acad. Sci. 82(4):205-208). The probability of seven out of seven young inheriting a simple recessive allele, however, is unlikely. Assuming the normal female is heterozygous and the unknown male is homozygous recessive, this probability is only one in 128 ($.5^7$). More likely these aberrations result from a shared environmental stress during development. Suboptimal temperatures, for example, have caused similar aberrations in *Python molurus* (Vinegar 1974. J. Herp., 30(1):72-74). The gravid female which produced these young may have experienced some environmental stress, including suboptimal temperature, before or after capture. The evolutionary significance of these aberrations remains unknown. I thank Larry Nienaber, Greg Hendricks, and the Department of Zoology at Arizona State University for support.

Submitted by **LEE H. SIMONS,** Department of Zoology, Arizona State University, Tempe, Arizona 85287, U.S.A. ●

ELAPHE GUTTATA GUTTATA (Corn Snake). **REPRODUCTION.** The largest clutch reported for *E. g. guttata* was 28 eggs for a specimen from Alachua Co., Florida (Iverson 1978. Florida Sci. 41:201-207). Ashton (1981. Handbook of Reptiles and Amphibians of Florida. Part One: The Snakes. Windward Publishing, Inc., Miami) gave an upper figure of 30 eggs for *E. g. guttata*. Larger clutches probably have been laid but not reported, especially considering the extensive captive propagation of this species.

On 11 April 1983 a female measuring 1500 mm TL (1290 mm SVL) with a mass of 891.5 g was captured 7.2 km W of Bunnell, Flagler Co., Florida. From 1400-0200 h on 9-10 June, 37 eggs (total mass = 334.1 g) were laid in a single adherent mass. Average egg mass was 9.0 g, and the female had a mass of 538.1 g after oviposition. Seven of the eggs averaged 32.3 mm long (range 29.8-33.8) and 21.8 mm wide (range 21.1-22.3). On 4-6 August 36 eggs hatched, and the remaining egg was opened on 7 August and found to contain a yolked embryo (296 mm TL) that subsequently died. On 9 August the 36 young averaged 318 mm TL (range 297-342) and 7.7 g (range 7.2-8.4).

A second female measuring 1380 mm TL (1190 mm SVL) with a mass of 588.9 g was captured on the same day at the same locality. After laying 30 fertile eggs and 2 small, yellow, misshapen eggs on 6 June, the female had a mass of 452.2 g. The 30 fertile eggs averaged 7.9 g, and 11 of the eggs averaged 30.7 mm long (range 29.2-32.1) and 21.7 mm wide (range 20.8-22.6). The eggs hatched on 1-2 August, and on 9 August the young averaged 300 mm TL (range 283-321) and 6.4 g (range 5.8-7.2).

Both females died in a viral epidemic in the author's collection; 60 of the offspring were released and 6 were maintained in several private collections.

Submitted by **KEVIN M. ENGE,** 1416 NW 21 Avenue, Gainesville, Florida 32605, U.S.A. ●

REGINA SEPTEMVITTATA (Queen Snake). **DICEPHALISM.** A dicephalic *Regina septemvittata* was found on 4 August 1985 in eastern Cobb County, Georgia by a Cobb County Water Department worker as it rested in a meter vault box. The neonate snake measured approximately 169 mm total length (121 mm S-V) with a well-formed umbilical scar indicating a recent birth. The two heads were joined near the right and left eyes of the left and right heads respectively. The lower jaw of the right head was unable to close properly due to the bifurcation and debris partially filled the mouth. The snake died shortly after being received by one of us (NJ) and was preserved.

Dicephalism is not uncommon in snakes. Clark and Tytle (1983. Herp. Review. 14(1):9) reported a dicephalic python. A dicephalic kingsnake was reported by Belfit and Nienaber (1983. Herp. Review. 14(4):121) who reviewed the literature on other cases of dicephaly. This is the first instance known to us of dicephalism in *R. septemvittata*. The specimen will be deposited in the University of Georgia Museum of Natural History. We wish to thank Mr. Ron McDaniel, Cobb County Water Department, for making this snake available to us.

STORERIA OCCIPITOMACULATA (Redbelly Snake). **PREDATION.** During a study of largemouth bass *(Micropterus salmoides)* trophic ecology from 1980-1985 in lakes Peter, Paul and Tuesday in Michigan's Upper Peninsula (Gogebic County), a *Storeria occipitomaculata* was recovered from the stomach of a bass collected 31 July 1981 (bass total length = 248 mm; mass = 218 g). The percent frequency of occurrence (F.O.) of *S. occipitomaculata* in the diet of largemouth bass was 0.06 (1724 bass stomachs were examined).

It was unusual to observe this species in the stomach of bass since the snakes are commonly associated with woodland habitats. (Vogt, R.C. 1981. Natural history of amphibians and reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee. 205 pp.). However, *S. occipitomaculata* have been observed beneath cover objects near the dike separating lakes Peter and Paul and in close proximity to other lakes in the general vicinity. Likelihood of contact between this species and aquatic predators may be greater in northern areas where lake shorelines are often forested and where numerous small lakes are characterized by a relatively high ratio of shoreline to surface area.

Other reptiles and amphibians found in bass stomachs during this study include *Thamnophis sirtalis* (4 individuals, F.O. = 0.23) *Notophthalmus viridescens* (1 individual, F.O. = 0.06) and several ranids (38 individuals, F.O. = 2.20, seven of which are tadpoles). Ranids commonly observed in the general study area include *R. clamitans, R. pipiens,* and *R. sylvatica*. Cochran (1982. Herp. Review 13:45-46) discussed predation on *R. pipiens* by largemouth bass.

The National Science Foundation provided funding for the project. We thank Philip Cochran for his suggested improvements to the manuscript.

THAMNOPHIS COUCHI HAMMONDI (Two-striped Garter Snake). **BEHAVIOR.** Head hiding in snakes is a distinctive defensive display in which the head is protected by concealing it under coils of the body. This behavioral strategy is widespread in snakes, and has been documented in at least 48 species (Carpenter and Ferguson 1977, *In:* Gans and Tinkle, Biology of the Reptilia, Vol. 7, pp. 335-554). In the genus *Thamnophis*, head hiding is known only in the plains garter snake, *T. radix* (Arnold and Bennett 1984, Anim. Behav. 32:1108-1118). In this note we report head hiding and other defensive behaviors observed in the two-striped garter snake, *T. c. hammondi*.

During three trips in April and May 1985 to the Santa Rosa Plateau Preserve in Riverside County, California, we captured eight individuals of *T. c. hammondi* along the edges of several vernal pools. To see if head hiding occurred in these snakes, we placed each individual on the ground and prodded the body with fingers. Six snakes attempted to flee, one tried to bite, and only two responded by hiding their heads under disorganized coils of the body. Defecation, dorso-ventral flattening, and flight into water were also observed. Most of the snakes, under continued molestation, raised the lateral coils of their bodies 0-2 cm above the substrate in a manner similar to but less exaggerated than that of crotaline snakes in response to ophiophagous snakes (Carpenter and Gillingham 1975, Herpetologica 31:293-302). Arnold and Bennett (1984) did not record defensive postures in *T. radix* in which the coils were raised above the substrate (except when biting).

That only 25% of the snakes responded by head hiding is not surprising since antipredator displays in garter snakes are highly variable within populations (Arnold and Bennett 1984). Arnold and Bennett (1984) have also shown that head hiding and other defensive displays in garter snakes are consistent in individuals and are in part heritable. Head hiding appears to be a common defensive mechanism in *T. c. hammondi*, and is probably widespread in the genus *Thamnophis*.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **COLORATION.** Albino common garter snakes (*Thamnophis sirtalis*) have been reported from British Columbia, Ontario, Connecticut, Indiana, Maryland, Michigan, Missouri, New York, Ohio, Pennsylvania, Washington, and West Virginia (Dyrkacz 1981. SSAR Herpetol. Circ. No. 11:1-31; Hensley 1959. Publ. Mus., Mich. State Univ. Biol. Ser. 1:133-159). To my knowledge, the following is the first documentation of albino garter snakes from Georgia.

In late April 1985 an amelanistic partial albino *Thamnophis s. sirtalis* (female, 43 cm SVL) was discovered by Mr. James Petty at his residence ¼ mi outside the city limits of Dalton, Whitfield Co., Georgia. The snake is entirely lacking dark pigmentation, but retains the characteristic yellow striping and lateral checkerboard of yellow/reddish spots. The background tissue where the dark pigment is missing has a bluish-pink aspect, and might best be described as lavender. The venter has the typical yellowish coloration. The eyes are pink and the tongue is red with white tips (the tongue tips would be black in a normally pigmented garter snake). The central portions of the frontal and parietal head scales, the temporal scales, and dorsolateral areas of the neck are slightly reddish. This snake was donated to the Atlanta Zoo where it is currently being maintained on a diet of earthworms and newborn mice.

Records of two other amelanistic partial albino *Thamnophis s. sirtalis* from Georgia were given to me by Mr. David Funderburk of the Fernbank Science Center, Decatur, Georgia. In July 1974 Cathie Brown of the Shoal Creek area of Dekalb County found a one foot amelanistic garter snake in her back yard. It was donated to Fernbank, where it was kept for several months until it died. In August 1976 another amelanistic garter snake caught in Dekalb County (no further information) was brought to Fernbank. It was ca. 18 inches long and lived only a few weeks in captivity. The ultimate disposition of these two specimens is unknown. However, the photos available (D.O. Funderburk, pers. comm.) show them to be identical in coloration to the Whitfield County specimen.

I thank James Petty and his family for caring for the snake and donating it. I thank David Funderburk for providing me with the information on the additional specimens, and Dr. H.B. Bechtel for providing literature references.

REPTILE CAGES

Designed with your needs in mind.

Desirable features of Herp-Huts:

- Should never have to be replaced.
- Molded in one piece of durable fiberglass, no seams, all corners rounded.
- Smooth finish facilitates easy cleaning and sterilization.
- Top front ridge, ideal for clamping heat lamp, if desired.
- Two vented louvers per cage (standard), designed to prevent scratches to animals and entrance of flies. Side or top mount possible.
- Side mounted vent plates make top/bottom interchangeable, creating pitch alternatives.
- Sloping front for easy viewing.
- Special vertical ridges on either side of cages "A" & "B" minimize possibility of small snakes getting wedged or escaping.
- Design suitable for reptile houses, mobile reptile exhibits, and reserve cages.
- ★ **Newest Option:** Feature requested - Hingeable front door with or without 5 inch safety glass shield.
- Traditional sliding glass front accessibity.

A New Approach to an Old Concept

★ *Newest Option: Hingeable Door* ★

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). **FORAGING.** In May 1985, 2 hatchling *C. serpentina* (carapace 3.7 and 3.4 cm) were collected at the same site from the Hillsborough River in Hillsborough Co., Florida. Once in captivity, the turtles were handfed assorted livebearing fish (with use of forceps) living in their 10 gallon aquarium.

At ca. 2200 h, 8 June 1985, I observed what appeared to be a common foraging behavior. The larger hatchling, while bottom crawling, stopped ca. 60 mm directly in front of a small (ca. 20 mm) *Xiphophorus helleri* hovering just over the substrate. The turtle withdrew its head aiming downwards and fully extended its forefeet upward and outward with palms outward. Vibrating its forefeet, it slowly approached the *X. helleri* using its hindlegs for locomotion. At ca. 30 mm from the turtle's head, the *X. helleri* oriented itself close to the turtle's right forefoot. At ca. 20 mm, the turtle lunged upward catching the fish by the peduncle and ate it tail first.

This has been repeated many times by both turtles using one or both forefeet seemingly to distract the fish. It is observed most frequently at night and when fewer than 20 fish are present. Any attempts by the turtles to extend or point their heads upward before a strike usually frighten the fish. Capturing the fish near the peduncle and eating it tail first occurred in each instance noted.

CLEMMYS MUHLENBERGI (Bog Turtle). **ELEVATION.** The elevation range of *Clemmys muhlenbergi* was summarized by Bury (1979. USDI. Fish & Wildlife Serv. Spec. Sci. Report No. 219, 9 pp.) as occurring from sea level to 1280 m (4200 ft). Nemuras (1974. Wildlife N.C. 38(2):13-15) gave the altitude range in North Carolina from 215 m (610 ft) in the piedmont to 1280 m (4200 ft) in the mountains. This 1280 m figure often cited by authors came from a male *C. muhlenbergi* collected 15 August 1916 in Avery Co., North Carolina by E. R. Dunn (1917. Bull. Nat. Mus. Natur. Hist. 37(23):593-634).

An adult female *C. muhlenbergi* (CL = 97.2 mm) was found in the fen on Bluff Mountain (N.C. Nature Conservancy Preserve), 3.2 km W West Jefferson, Ashe Co., North Carolina on 3 June 1985 at 1340 h at an elevation of 1373 m (4500 ft). The turtle was observed digging in the mud next to a small rivulet. The air temperature was 30.0° C and the cloacal temperature was 27.0° C.

This elevation (1373 m) surpasses the old record by nearly 100 m and the turtle confirms past sightings of *C. muhlenbergi* at this locality. Several other high elevation bogs presently under survey may also support populations of bog turtles.

A Kodachrome 35 mm slide (#DWH 85.42) has been deposited in the North Carolina State Museum. A grant from the North Carolina Nature Conservancy supported field work, and the North Carolina Natural Heritage Program provided assistance.

Submitted by **DENNIS W. HERMAN,** Department of Herpetology, Atlanta Zoological Park, 800 Cherokee Avenue SE, Atlanta, Georgia 30315 and **RUBY D. PHARR,** Department of Biology, Western Piedmont Community College, Morganton, North Carolina 28655, U.S.A. ●

CLEMMYS MUHLENBERGI (Bog Turtle). **NEST PREDATION.** Raccoons, skunks, foxes, dogs, and other large predators have been reported as predators on nests, young, and adults of *C. muhlenbergi* by Ernst and Barbour (1972. Turtles of the United States. The Univ. Press of Kentucky. Lexington. 347 pp.) and Nemuras (1974. Wildl. N.C. 38(2):13-15 and 1976. Defenders Wildl. 51(1):38-39).

On 31 July 1985, seven eggs in a bog turtle nest disappeared from a naturalistic bog setup at Zoo Atlanta. No disturbance to the nest itself was observed. A second *C. muhlenbergi* nest in a separate bog setup was checked and its one egg was found intact.

In an attempt to determine the source of predation, an infertile spotted turtle *(Clemmys guttata)* egg and the shell of a recently hatched spotted turtle were placed in the original *C. muhlenbergi* nest and covered with sphagnum moss. The following morning (0910 h) both the infertile egg and the bog turtle egg from the second nest were missing. Neither nest was noticeably disturbed; the moss cover was intact. A search of the immediate area yielded tracks of an oppossum, *Didelphis marsupialis*, on an ant mound (R.H. Hunt identification). This observation and the fact that a population of oppossums is known to exist on the zoo grounds suggested that we had solved the mystery.

This occurrence of nest predation adds the oppossum to the list of potential predators of *C. muhlenbergi* and *C. guttata*.

Submitted by **DENNIS W. HERMAN,** Department of Herpetology, Zoo Atlanta, 800 Cherokee Avenue SE, Atlanta, Georgia 30315, U.S.A. ●

CLEMMYS MUHLENBERGI (Bog Turtle). **REPRODUCTION.** Reproduction in the bog turtle was summarized by Bury (1979. USDI. Fish & Wildlife Service. Spec. Sci. Report-Wildl. No. 219:1-9) with no records then known of multiple clutches in *C. muhlenbergi*. Carr (1952. Handbook of Turtles. Cornell Univ. Press. Ithaca, N.Y. 542 pp.) stated (p. 132) "a captive specimen kept by Wright that laid 2 eggs, one on June 5 and another a month later; a third was found in the oviduct." This was probably a result of the stress of capture, as I have observed for wild-caught gravid *C. muhlenbergi* (unpub. obs.), and not a true case of multiple clutching. The maximum clutch size for the bog turtle was commented on by Herman (1983. SSAR Herp. Review 14(4):122) when a turtle housed at Zoo Atlanta deposited six eggs in May 1983. An additional clutch of six eggs was deposited by the same turtle in May 1984.

On 30 May 1985 this female bog turtle deposited two eggs in a shallow nest at the base of a sedge clump in an outdoor bog setup. A triple beam balance and vernier calipers were used to determine the following data for the eggs:

Length (mm)	31.8 and 32.3	($\bar{X}$ = 32.1)
Width (mm)	15.8 and 16.1	($\bar{X}$ = 16.0)
Mass (g)	5.1 and 5.2	($\bar{X}$ = 5.2)

The progress of the incubating eggs was checked three times weekly. On 30 June 1985 a second, freshly deposited clutch containing five eggs was discovered in the same nest cavity. The five eggs were noticeably smaller than those of clutch #1. Measurements were as follows (middle column = range):

Length (mm)	21.8-25.7	($\bar{X}$ = 23.5)
Width (mm)	13.6-14.4	($\bar{X}$ = 13.9)
Mass (g)	2.5-3.1	($\bar{X}$ = 2.8)

This is the first reported case of multiple clutching in *C. muhlenbergi* and the seasonal total of seven eggs is probably a record for the species. Contributing factors to this multiple clutching are not known.

Submitted by **DENNIS W. HERMAN,** Department of Herpetology, Zoo Atlanta, 800 Cherokee Avenue SE, Atlanta, Georgia 30315, U.S.A. ●

DERMOCHELYS CORIACEA (Leatherback sea turtle). **COPULATION.** On 5 April 1985 at 1630 h, while conducting a turtle and manatee survey in the Culebra Island Archipelago, Puerto Rico, we encountered a pair of mating leatherback sea turtles *(D. coriacea)* approximately 200 m northeast of Cayo Geniqui. The pair remained intermittently in view for ca. 20 min. When first sighted, in 44 m of water, the two turtles were coming to the surface about five m apart. The female remained stationary at the surface and the male moved rapidly toward her, with his head held high above the water. When he reached a point one m behind her, he lunged forward, lodging the center of his plastron on the posterior dorsal area of her carapace. The female immediately sounded, leaving the male at the surface. The male then took a quick audible breath and rapidly sounded along the same path of descent taken by the female. When the two emerged a second time they were only two meters apart. The male immediately lunged onto the back of the female, just as before. Again the female sounded, but this time with less zeal than before. When the turtles appeared at the surface a third time they were very close to each other and the female showed little reaction when the male lunged up onto her back, positioning the center of his plastron just posterior to the center of her carapace. His weight forced her body below the surface, and at that point both animals began to list, and then to roll laterally back and forth. Each time the male rolled, his tail and semi-erect penis, which had been angled down toward the trailing edge of the female's shell, lifted out of the water and was clearly

visible. The two then separated, sounded, and after a few minutes came to the surface for a fourth time, within two m of each other. Both appeared to be less agitated than on previous surfacings. Just as before, the male shoved himself up on top of the female, this time his movements appearing more coordinated. His tail curved under the female's shell and beneath the base of her tail. Her fore-flippers became rigid and were elevated slightly above the surface of the water, and the fore-flippers and neck of the male became rigid. At this point the two turtles quivered slightly, and then together, slowly submerged. They were lost from view at a depth of ca. four m and were together at that time.

We have not been able to locate previously published information on mating in *Dermochelys*. There are minor nesting colonies on several islands of this area, and no way of knowing the source of this pair or the subsequent nesting site of the female.

Submitted by **THOMAS CARR** and **NICOLE CARR,** Florida State Museum, Gainesville, Florida 32611, U.S.A. ●

STERNOTHERUS MINOR MINOR (Loggerhead Musk Turtle). **SIZE.** Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin Co., Boston. 429 pp.) gave a maximum size of 135 mm CL for *S. m. minor*. Iverson (1977. Copeia 1977:502-517) reported that females grow significantly larger than males and that of 1072 turtles examined, the largest female (Aucilla River, Florida) measured 132.9 mm CL and the largest male (Rainbow Run, Florida) measured 124.25 mm CL.

On 21 March 1985, a female *S. m. minor* with a straight-line CL of 145 mm was collected in Rainbow Run ca. 4 km north of Dunnellon, Marion Co., Florida. Carapace width and height at the juncture of the sixth and seventh marginals were 90 mm and 52 mm, respectively. The specimen had a mass of 401.3 g three weeks after capture. A male *S. m. minor* collected on the same day had a CL of 137 mm, despite missing ca. 5 mm of its pygal bone. Carapace width and height were 92 mm and 49 mm, respectively, and its mass was 379.3 g. These two specimens represent the largest individuals in a series of 1942 *S. m. minor* collected by the junior author in North Florida spring runs.

Submitted by **KEVIN M. ENGE,** 1416 NW 21 Avenue, Gainesville, Florida 32605, and **DOUGLAS R. FOSTER,** 3131 NW 11 Street, Gainesville, Florida 32609, U.S.A. ●

TERRAPENE CAROLINA CAROLINA (Eastern box turtle) **TWINNING.** Twinning in oviparous reptiles is well known in snakes. It is however, infrequently reported in turtles. Plymale et al. (1980. Flor. Scientist 43(2):97-102) reported chelonian twinning known from 62 specimens in five families, nine genera and 10 species, the highest instance of which was discussed by Yntema (1970. Anat. Record 166(3):491-498) in *Chelydra serpentina* (23 out of 2228 eggs).

Twinning in *Terrapene carolina* was described previously for *T. c. major* by Tucker and Funk (1976. Flor. Scientist 39(4):238-239) and for *T. c. triunquis* by Crooks and Smith (1958. Herpetologica 14:170-171).

On 19 August 1984 the author opened an obviously bad egg laid by a captive *T. c. carolina* (exact date of deposition unknown) and removed dead twin embryos joined at the yolk sack. The well-advanced embryos measured 19.0 and 20.0 mm in length.

Submitted by **HENRY COHEN,** 24 St. Johns Pl., Buffalo, New York 14201, U.S.A. ●

TRACHEMYS SCRIPTA CATASPILA (Huastecan Slider). **REPRODUCTION.** A gravid female *Trachemys scripta cataspila* was captured southeast of Rancho Nuevo, Municipio de Aldama, Tamaulipas, Mexico (23° 11' N, 97° 47' W) on 24 June 1981. The female had straight, mid-line lengths of 224 mm (carapace) and 205 mm (plastron), and a mass of approximately 1800 g. On 1 July, oxytocin injections totalling 1.4 cc (20 I.U./cc) were administered over a three hour period according to procedures modified from those of Ewert and Legler (1978. Herpetologica 34: 314-318). A parchment-shelled, ovoid egg was deposited after three hours and 40 minutes, followed by a second egg 12 minutes later. Repeated palpation between injections indicated that both eggs had originated in the left oviduct, and that at least one more egg was low in the right oviduct. However, a final injection of 0.2 cc oxytocin 13 minutes later failed to induce further oviposition. Measurements for these eggs were 41.7 X 26.5 mm, 16.92 g, and 43.6 X 27.3 mm, 18.85 g. Due to desiccation during incubation, the eggs did not develop. The female was subsequently released.

On 9 July 1981, a hatchling *T. s. cataspila* was found freshly killed less than 300 meters east of the site where the aforementioned gravid female was captured. The hatchling was in good condition, with the following dimensions: straight, mid-line carapace length = 39.6 mm, straight, mid-line plastron length = 35.2 mm, carapace width at marginals 5-6 = 35.9 mm, minimum bridge length = 11.5 mm, and maximum shell depth = 15.7 mm. The specimen retained unabsorbed yolk and was presumed to have recently hatched. It was found ca. 50 m from a permanent stream where adults had often been seen basking and surfacing. Hatchling turtles were observed in this same stream on 9, 11, and 12 July, 1981.

These observations provide natural emergence data. Assuming an incubation period of two to three months (similar to other subspecies of *T. scripta*) the eggs from which these hatchlings emerged were likely deposited in April or May. Together with the gravid female, this suggests a nesting season which lasts from April until late June. This estimated nesting season falls within the range given by Rosado (1967. Intl. Turt. and Tort. Soc. J. 1(3):16-19,42) for *T. s. venusta*, the closest occurring subspecies of *T. scripta* to the south.

We have used the vernacular name Huastecan slider in recognition of the coincidental range of *T. s. cataspila* with the pre-Columbian Huastec Indian culture. The hatchling will be deposited in the National Museum of Natural History (USNM). We gratefully acknowledge the assistance of Pat Burchfield, and also thank the U.S. Fish and Wildlife Service and Mexico's Instituto Nacional de Pesca for the opportunity to have worked at Rancho Nuevo.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

HAMPTOPHRYNE BOLIVIANA. VENEZUELA: ESTADO BOLIVAR: Reserva Forestal Rio Grande, Rio Grande at road to El Palmar (8° 00'N, 61° 40'W), 266 m. 16 December 1980. J. Cadle. Verified by Alfredo Paolillo O. Museum of Vertebrate Zoology, Univ. of California, Berkeley (MVZ 176018). First record for Venezuela. Duellman (1981. Amphibia. *In:* Hurlbert, Rodríguez and Santos (eds.) Aqua-

tic Biota of Tropical South America, Part 2: Anarthropoda. San Diego State Univ.: 230-245.) included "Venezuela" in the range of the species, but no specimen was cited. This species was mentioned from all Amazonian and Guianan countries, excepting Colombia and Venezuela (D. Frost, (ed.) 1985. Amphibian Species of the World. Allen Press & Assoc. Syst. Coll., Lawrence, Kansas 732 p.).

Study financed by the Smithsonian Institution (Department of Vertebrate Zoology); I thank R. McDiarmid for help and H. Greene for the MVZ loan.

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Frio Co: Panther Hollow Ranch, 9.7 km NNW I-35 and FM 117 intersection. 29 April 1985. J. S. McCord, Jr. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA A-17649). New county record. Fills gap between Uvalde and La Salle counties (Raun and Gehlbach 1972. Dallas Mus. Nat. Hist. Bull. No. 2).

I acknowledge help of the Texas Herpetological Society.

Submitted by **JOHN S. McCORD, JR.,** Box 19498, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019, U.S.A. ●

RANA PIPIENS (Northern Leopard Frog). USA: MISSOURI: Atchison Co: 9.6 km SW of Hamburg (Iowa) and SW of county highway V (T66N, R43W, Sec. 11). 30 May 1985. Tom R. Johnson. Verified by John B. Hess and Carl Gerhardt. Museum of Natural History, University of Kansas, (KU 204082-204086). New state record. Extends range into extreme northwest Missouri (Johnson 1977. Amphibians of Missouri. Univ. Kansas Mus. Nat. Hist., Publ. Educ. Ser. (6):1-142.

Submitted by **TOM R. JOHNSON,** Missouri Department of Conservation, P.O. Box 180, Jefferson City, Missouri 65102, U.S.A. ●

CAUDATA

AMBYSTOMA JEFFERSONIANUM (Jefferson Salamander). USA: NEW HAMPSHIRE: Chester Co: Winchester, 1.6 km E Scotland Rd on State Hwy 119. 3 May 1984. T. French and L. Master. Verified by J.P. Bogart. Museum of Comparative Zoology, Harvard University (MCZ 107955). First verified record for state. This specimen was identified by external morphology, erythrocyte nuclear volume, electrophoresis, and chromosome number.

Previous New Hampshire records refer to specimens taken before the recognition of *A. laterale* and triploid members of the complex. Examination of existing specimens (Univ. of Michigan Museum of Zoology (UMMZ) 84515-84516, MCZ 979) and printed descriptions (Oliver and Bailey 1939. Biological Survey of the Connecticut Watershed. Survey Report no. 4:195-217. New Hampshire Fish and Game Dept.; Stewart 1951. The Caudata of Durham, New Hampshire and Adjoining Localities. Unpublished master's thesis, Univ. of N.H.) suggest that all previous specimens from New Hampshire have been *A. laterale* and possibly the triploid, *A. tremblayi*. Twenty-one specimens collected in 1983 by the authors were identified by J. Bogart (by chromosome number) as 8 *A. laterale* (MCZ 107619-107621, 107623, 107632; UMMZ 176841-176842) from Hillsborough, Rockingham and Strafford counties and 13 *A. tremblayi* (MCZ 107622, 107624, 107626-107627, 107629-107631, 107952; UMMZ 176836-176840) from Hillsborough and Rockingham counties.

Submitted by **THOMAS W. FRENCH,** Massachusetts Division of Fisheries and Wildlife, 100 Cambridge Street, Boston, Massachusetts 02202 and **LAWRENCE L. MASTER,** The Nature Conservancy, 294 Washington Street, Boston, Massachusetts 02108, U.S.A. ●

AMBYSTOMA LATERALE (Blue-spotted Salamander). USA: WISCONSIN: Florence Co: near Pembine. 25 August 1985. D. Engels. Verified by P.A. Cochran. University of Wisconsin-Madison Zoology Museum (UWZM H22630). Langlade Co: In woods along Wolf River near Hollister (T-32N, R-14E, Sec. 19). 7 September 1985. P.A. Cochran. Verified by P. A. Cochran (UWZM H22629). New county records (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Publ. Mus. 205 pp.).

Submitted by **PHILIP A. COCHRAN** and **JAMES R. HODGSON,** Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115, U.S.A. ●

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). USA: RHODE ISLAND: Providence Co: North Foster, 225 m. 3 September 1985. James Lazell. Verified by J. Lazell. Museum of Comparative Zoology, Harvard University (MCZ 107821). New state record. Ca. 40 km ENE closest Connecticut locality (Storrs, Tolland Co: Brandon 1966. Illinois Biol. Monogr. 35:1-86). Ca. 55 km SE closest Massachusetts locality (Palmer, Hampden Co: MCZ 107866). Some published maps have anticipated this discovery: Brandon (ibid, Fig. 6, p. 20 and Fig. 15, p. 46) included part of Rhode Island, but examined no specimens. DeGraaf and Rudis (1983. Amphibians and Reptiles of New England, Univ. Mass. Press, Amherst) inform one of us (CR: pers. comm.) that the dot on their map, and other marks in Rhode Island, are printing errors.

Submitted by **J. D. LAZELL, JR.,** The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835 and **CHRISTOPHER RAITHEL,** Natural Heritage Program, RI-DEM, 22 Hayes Street, Providence, Rhode Island 02908, U.S.A. ●

SAURIA

CNEMIDOPHORUS LAREDOENSIS (Laredo Striped Whiptail). MEXICO: TAMAULIPAS: Nuevo Laredo, SE international bridge ca. 0.5 km from Rio Grande. 28 May 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, J. M. Britton, and P. J. Polechla, Jr. Department of Zoology Collection, University of Arkansas (UADZ 1064-1075). Ciudad Miguel Aleman, N side of town near movie theater and baseball field. 26 May 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, J. M. Britton, and P. J. Polechla, Jr. (UADZ 1076-1100). Reynosa, S international bridge in suburbs near canals. 27 May 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, J. M. Britton, and P. J. Polechla, Jr. (UADZ 1112-1115). Nuevo Progreso, NW international bridge near Rio Grande. 22 July 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, and J. M. Britton. (UADZ 1327-1328). All verified by J. M. Walker. First records in Mexico.

USA: TEXAS: LaSalle Co: Encinal. 8 September 1985. J. M. Walker, J. E. Cordes, and P. J. Polechla, Jr. (UADZ 1365). Webb Co: 4.5 km S Chacon Creek Arroyo, then 1.6 km W U. S. Highway 83 near Rio Grande. 16 June 1984. J. M. Walker, S. E. Trauth, J. E. Cordes, and B. Kuss. University of Kansas (KU 199854-199856). Zapata Co: Zapata, vacant lot several blocks S Dairy Queen and U. S. 83. 13 July 1984. J. M. Walker, J. E. Cordes, and J. M. Britton. (KU 199919-199920). Starr Co: 2.5 km from Falcon Lake Dam. 26 May 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, J. M. Britton, and P. J. Polechla, Jr. (UADZ 1042-1045). Hidalgo Co: Los Ebanos, between town and Rio Grande. 28 May 1985. J. M. Walker, S. E. Trauth, J. E. Cordes, J. M. Britton, and P. J. Polechla, Jr. (UADZ 1054-1058). All verified by J. M. Walker. The LaSalle County record establishes the presence in the Nueces River drainage, a distance of 64 km from the Rio Grande. All other known records listed herein or published (McCrystal, Dean, and Dixon 1985. Texas Jour. Science 36(4):283-284, and Dryden 1985. SSAR Herp. Review 16(2):60) lie within a narrow riverine zone of about 10 km in width and 250 road km in length on both sides of the Rio Grande between Nuevo Laredo-Laredo and Nuevo Progreso-Progreso. Collections in Texas were made under authority of Texas Parks and Wildlife permit No. 61.

SPHAERODACTYLUS ELEGANS (Ashy Gecko). USA: FLORIDA: Monroe Co: Boot Key (near Marathon), along road 2 km south of bridge. 3 January 1985. J. H. Epler. Verified by Larry David Wilson. Museum of Natural History, University of Kansas (KU 204151). Three specimens observed at collection site 60 km (by air) NE of previous record at Big Coppitt Key.

Submitted by **J. H. EPLER,** Department of Biological Science, Florida State University, Tallahassee, Florida 32306, U.S.A. ●

SERPENTES

ARRHYTON TAENIATUM. CUBA: GUANTÁNAMO PROVINCE: Guantánamo Bay U.S. Naval Base, Cuzco Beach, west side of access road, 20 meters from splash zone. 8 October 1985. B. I. Crother. Verified by A. Schwartz. Albert Schwartz Collection (ASFS V50466). First record for Guantánamo Bay area (Lando and Williams 1969. Studies on the Fauna of Curacao and other Caribbean Islands. 116: 159-201), and extends range both south and west on Cuba. Although *A. taeniatum* is considered a mesic habitat dweller (Schwartz, pers. comm.), Guantánamo Bay is a xeric rain shadow habitat.

Submitted by **BRIAN I. CROTHER,** Department of Biology, University of Miami, P.O. Box 249118, Coral Gables, Florida 33124, U.S.A. ●

ERYTHROLAMPRUS PSEUDOCORALLUS (False Coral Snake). VENEZUELA: ESTADO MERIDA: Distrito Andrés Bello: El Amacao, 7 km SE La Azulita. 15 June 1985, Alfredo Lacroix. Verified by Juan Elías García. Colección de Vertebrados, Universidad de Los Andes. Mérida (ULAM IV-2819). First record for Mérida State and the southernmost locality, extending the known range approximately 220 km SE of Kunana, Zulia State (Marcuzzi 1950, Nov. Cient. La Salle, Caracas, Ser. Zool. (3):1-20). This species, previously considered endemic to the mountains of Zulia State, (Roze 1966. La Taxonomia y Zoogeografia de los Ofidios en Venezuela. Univ. Cent. Ven., Caracas) represents one of the few non-widespread species shared by the Sierra de Perijá and the Venezuelan Andes, and the only snake shared exclusively by these two mountain ranges. Contribution No. 1 of the Sierra de Perijá Herpetological Program.

DISTRIBUTION RECORDS FOR AMPHIBIANS AND REPTILES IN BELIZE, CENTRAL AMERICA

Field work in Belize during 1984-1985 has yielded several new district records and range extensions, herein reported. The specimens (or voucher photographs) cited are deposited in the Carnegie Museum of Natural History (CM), Florida State Museum (UF), or Appalachian State University (ASU) collections. Identifications were verified by C. J. McCoy.

CENTROLENELLA FLEISCHMANNI. Toledo Dist: Blue Creek Village. August, 1984. R. W. Van Devender. (Photographs, CM Acc. 33025.27-33025.29). New district record. Extends range ca. 80.5 km S of previous Belize records in Cayo Dist (Henderson and Hoevers 1975. Milwaukee Publ. Mus. Contr. Biol. Geol. 5:13; Olson 1984. SSAR Herp. Review 15(3): 76).

GASTROPHRYNE ELEGANS. Belize Dist: Parrot's Wood, Mile 30.5 on Western Hwy. October, 1984. R. E. Ashton, Jr. (CM 109027). Toledo Dist: Blue Creek Village. 20 March 1984. R. W. Van Devender. (ASU 10177). New district records. Extend range about 97 km S and 217 km SSW, respectively, of the only previous Belize locality (Albion Island, Orange Walk Dist: Henderson and Hoevers 1975. op. cit.:16).

TRIPRION PETASATUS. Cayo Dist: 2.4-8.0 km S Belmopan on Hummingbird Hwy. 25 June 1985. C. J. McCoy, E. J. Censky, P. Freed and M. Freed. (CM 112160-112161, 112169-112170). New district record. Extends range ca. 97 km SSW Orange Walk Town, Orange Walk Dist (Hoevers and Henderson 1974. Milwaukee Publ. Mus. Contr. Biol. Geol. 2:1).

STAUROTYPUS TRIPORCATUS. Toledo Dist: The Dump, about 0.8 km W jct Southern Hwy and Punta Gorda-San Antonio Rd. 28 March 1984. C. J. McCoy, et al. (CM 105875-105878). Ca. 3.2 km SE Big Falls. 1 April 1984. C. J. McCoy et al. (CM 105898). New district record. Fills hiatus between records from central Belize (Neill and Allen 1959. Publ. Res. Div. Ross Allen's Reptile Inst. 2(1):28) and the northern coast of Honduras (Meyer and Wilson 1973. Los Angeles Co. Mus. Nat. Hist. Contr. Sci. (244):5).

CNEMIDOPHORUS COZUMELA. Toledo Dist: Las Lomitas, ca. 6.4 km S Swasey Branch on Southern Hwy. 8-9 April 1984. C. J. McCoy et al. (CM 105935). New district record. Extends range about 120 km S Manatee, Belize Dist (Henderson and Hoevers 1975. op. cit.:32).

EUMECES SCHWARTZEI. Cayo Dist: ca. 4.8 km S Belmopan on Hummingbird Hwy. E. J. Censky and C. J. McCoy. 26 June 1985. (CM 112183). New district record, second specimen from Belize. Extends range 58 km SE Gallon Jug, Orange Walk Dist (Henderson and Hoevers 1975. op. cit.:29).

LEPIDOPHYMA FLAVIMACULATA. Toledo Dist: Blue Creek Village. 9-11 August 1984. R. W. Van Devender. (Photograph, CM Acc. 33025.18). New district record. Extends range 72 km SW southernmost localities in Stann Creek Dist (Schmidt 1941. Zool. Ser. Field Mus. Nat. Hist. 22(8):495).

ADELPHICOS QUADRIVIRGATUS. Cayo Dist: Blancaneaux Lodge, 16.1 km N Augustine. 20 April 1972. J. F. Jackson. (UF 60685). New district record. Second locality (third specimen) for Belize (Smith 1942. Proc. Rochester Acad. Sci. 8:188-192), and the first from Mountain Pine Ridge.

DRYADOPHIS MELANOLOMUS. Toledo Dist: ca. 3.2 km SE Big Fall, Rio Grande. 1983. J. Chen. (CM 105886). New district record. Extends range about 80.5 km SSE Augustine, Cayo Dist (Neill 1956. Bull. Florida State Mus. 9(3):77-130).

CONIOPHANES SCHMIDTI. Cayo Dist: Macal River at Guacamallo Bridge. 22-25 June 1985. P. Freed, M. Freed, C. J. McCoy and E. J. Censky. (CM 112148). Second specimen from Belize. Extends range southward beyond Mountain Pine Ridge (Neill and Allen 1960. Herpetologica 16(3):145-146).

OXYRHOPUS PETOLA. Belize Dist: Parrot's Wood, Mile 30.5 on Western Hwy. October, 1984. D. Weyer. (CM 109026). New district record. Extends range 64 km ENE Augustine, Cayo Dist (Neill and Allen 1959. op. cit.: 55-56).

TANTILLA SCHISTOSA. Belize Dist: between Hattieville and Burrell Boom. 17 March 1984. C. J. McCoy et al. (CM 105923). New district record. Extends range ca. 88.5 km ENE Xunantunich, Cayo Dist (Neill and Allen 1962. Herpetologica 18(2):88-89).

Acknowledgments. Field work was supported by grants from the O'Neil Fund and the Netting Research Fund, Carnegie Museum of Natural History. Ray E. Ashton, Jr. of International Expeditions, Inc. provided logistical aid. We thank Dora Weyer and the Belize Audubon Society for support, O. Rosado of the Belize Ministry of Natural Resources for issuing collecting permits, and P. Meylan, Florida State Museum, for loan of a specimen. MORE DISTRIBUTIONAL RECORDS OF AMPHIBIANS AND REPTILES FROM TEXAS

The following presents new county records for 12 amphibian and 36 reptilian taxa from 48 counties of Texas. These records complement the distributional data in Raun and Gehlbach (1972), Karges (1978, 1979, 1981, 1982), McAllister et al. (1983), McAllister and Ward (in press) and others. The authors verified identifications. Specimens are deposited in the Dallas Museum of Natural History (DMNH). Appreciation is extended to Drs. Richard Fullington and William E. Wilson of the DMNH for allowing access to the collection.

CAUDATA

Ambystoma tigrinum mavortium (Barred Tiger Salamander). Winkler Co: 1.6 km NE of junction TX 18 and FM 1232. 2 May 1976. W. Seifert. (DMNH 4582).

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander). Robertson Co: 3.2 km SW Franklin. 28 April 1969. T. L. Hibbitts. (DMNH 4274).

ANURA

Scaphiopus bombifrons (Plains Spadefoot). Garza Co: 8.9 km NE Post on FM 651. 17 May 1977. W. Seifert. (DMNH 4654). Wichita Co: 3.2 km E Burkburnett. 20 May 1967. W. Seifert. (DMNH 179).

Scaphiopus couchii (Couch's Spadefoot). Coleman Co: 17.7 km ENE Coleman. 30 April 1977. W. Seifert. (DMNH 4660). Crockett Co: 6.4 km W Ozona. 20 June 1957. D. C. Carter. (DMNH 3380). Sutton Co: 11.3 km WNW Sonora. 20 June 1957. D. C. Carter. (DMNH 3379).

Scaphiopus hammondii (Western Spadefoot). Randall Co: 12.9 km W Wayside on FM 285. 29 June 1973. T. L. Hibbitts. (DMNH 4415).

Scaphiopus holbrookii hurterii (Hurter's Spadefoot). Hidalgo Co: 24.1 km S McCook on FM 681. 10 April 1971. W. Seifert. (DMNH 764). Wood Co: 8.0 km NW Mineola. Collection date unknown. O. H. Sanders. (DMNH 2203).

Hyla versicolor/chrysoscelis (Gray Treefrog/Cope's Gray Treefrog). Waller Co: 16.1 km N Hempstead. 17 April 1958. D. C. Carter. (DMNH 3130). Due to the lack of recorded field calls or preparations of chromosomes, species discrimination between *H. versicolor* and *H. chrysoscelis* is not possible.

Bufo cognatus (Great Plains Toad). Culberson Co: 16.1 km N Van Horn. 10 September 1975. W. Seifert. (DMNH 2339).

Bufo punctatus (Red-spotted Toad). Crockett Co: 14.5 km E Sheffield. 21 June 1957. D. C. Carter. (DMNH 2680). Johnson Co: Cleburne State Recreation Area. 17 May 1959. W. B. Stallcup. (DMNH 3258).

Rana berlandieri (Rio Grande Leopard Frog). Winkler Co: 8.1 km NE Kermit. 1 May 1976. W. Seifert. (DMNH 4586). Extends the known range of this species north of a Ward County locality (Hillis 1981).

Rana blairi (Plains Leopard Frog). Garza Co: 7.0 km SE Poston on U.S. 84. 16 May 1977. W. Seifert. (DMNH 4650). Haskell Co: 4.8 km NE Haskell. 4 September 1966. Kimbrough and Van Nordstrand. (DMNH 3484).

Rana sphenocephala (Southern Leopard Frog). Hopkins Co: 6.0 km S Sulfur Bluff on FM 69. 18 September 1976. W. Seifert. (DMNH 4599).

TESTUDINES

Sternotherus carinatus (Razorback Musk Turtle). Anderson Co: 12.9 km S Palestine, N shore of Crystal Lake. 5 April 1966. T. D. Newsom. (DMNH 3850). Kaufman Co: 1.6 km S Kemp, King's Creek tributary. 8 June 1974. W. Seifert. (DMNH 2077).

Pseudemys scripta elegans (Red-eared Slider). Grayson Co: Eisenhower State Recreation Area, Lake Texoma. 11 April 1968. J. G. Rankin. (DMNH 3868).

Terrapene carolina triunguis (Three-toed Box Turtle). Ellis Co: 4.8 km SW Ellis. 31 March 1968. J. W. Skinner. (DMNH 3858). Hopkins Co: 30.4 km E Greenville. 7 May 1961. Kimbrough and McDonald. (DMNH 3908). San Jacinto Co: 8.0 km S Pointblank, Sam Houston National Forest. 24 April 1974. W. Seifert. (DMNH 1547).

Terrapene ornata ornata (Ornate Box Turtle). Crosby Co: 38.6 km NE Post. 19 May 1977. W. Seifert. (DMNH 4658).

SAURIA

Phrynosoma cornutum (Texas Horned Lizard). Glasscock Co: J. G. Carter Farm (precise locality not recorded). 9 May 1964. J. G. Carter. (DMNH 2020).

Phrynosoma modestum (Roundtail Horned Lizard). Ward Co: Pyote Air Force Base, Pyote. 1 May 1976. W. Seifert. (DMNH 4580).

Sceloporus olivaceous (Texas Spiny Lizard). Aransas Co: 1.6 km N entrance to Goose Island Recreation Area on Park Rd. 13. 1 June 1973. R. D. Specian. (DMNH 1247).

Sceloporus undulatus consobrinus (Southern Prairie Lizard). Runnels Co: 3.2 km N Wingate. 25 March 1967. C. L. Green. (DMNH 4148). Ward Co: Old Pyote Air Force Base, Pyote. 1 May 1976. T. L. Hibbitts. (DMNH 4457).

Sceloporus undulatus hyacinthinus (Northern Fence Lizard). Bee Co: 3.2 km N Beeville on U.S. 181. 2 April 1953. Collector unknown. (DMNH 3742). Van Zandt Co: 8.0 km S Grand Saline. 18 April 1976. W. Seifert. (DMNH 4683).

Eumeces laticeps (Broadhead Skink). Kaufman Co: 1.6 km E Kemp, Clark Farm. 24 July 1971. W. Seifert. (DMNH 884). Madison Co: vicinity Madisonville. 2 May 1969. J. Gent. (DMNH 4268).

Eumeces obsoletus (Great Plains Skink). Clay Co: 12.9 km S Jolly, Lake Arrowhead. 13 July 1972. W. Seifert. (DMNH 1074).

Cnemidophorus gularis gularis (Texas Spotted Whiptail). Garza Co: 7.2 km SE Post on U.S. 84. 18 May 1977. W. Seifert. (DMNH 4657).

Cnemidophorus sexlineatus sexlineatus (Six-lined Racerunner). Limestone Co: Fort Parker State Recreation Area. 16 April 1966. R. Davis. (DMNH 3004).

SERPENTES

Coluber constrictor priapus (Southern Black Racer). Upshur Co: 1.6 km N Gilmer on U.S. 271. 23 April 1950. J. Powell. (DMNH 1840).

Diadophis punctatus arnyi (Prairie Ringneck Snake). Freestone Co: 10.5 km W Cayuga, Trinity and Young Rivers. 27 November 1965. T. L. Hibbitts. (DMNH 4117). Grayson Co: 4.8 km NW Denison, Eisenhower State Recreation Area. 11 April 1968 and 3 March 1974. W. Seifert and J. G. Rankin. (DMNH 2867, 1467).

Diadophis punctatus stictogenys (Mississippi Ringneck Snake). Van Zandt Co: 16.0 km NW Brownsboro. 12 October 1976. J. Lanthum. (DMNH 4494).

Elaphe guttata emoryi (Great Plains Rat Snake). Collin Co: Joe G's Food Store, Wylie. 29 May 1980. T. L. Hibbitts. (DMNH 5257). Garza Co: 3.7 km S Post on U.S. 84. 17 May 1977. W. Seifert. (DMNH 4656). Nacogdoches Co: 0.5 km S Nacogdoches on TX Loop 224. 14 April 1977. A. Alexander. (DMNH 5276). Van Zandt Co: 16.0 km NW Brownsboro near Calendar Lake. 23 April 1975. T. L. Hibbitts. (DMNH 4482). Raymond and Hardy (1983) reported that "populations usually assigned to *E. g. emoryi* are in western and central Texas, eastward to a line from approximately Houston to Dallas." In addition, Conant (loc. cit.) noted that intergrade *E. g. emoryi* X *guttata* occur in extreme eastcentral Texas north to southern Arkansas. Based upon coloration and number of ventral plus subcaudal scales, the Nacogdoches County specimen appears to be an intergrade. Furthermore, the Van Zandt County specimen falls within a distributional gap (see Raymond and Hardy, loc. cit.) in eastern Texas.

Heterodon nasicus kennerlyi (Mexican Hognose Snake). Hudspeth Co: 8.0 km N Hueco Tanks Rd. near El Paso County line. 20 June 1973. J. Davis. (DMNH 1459).

Heterodon platyrhinos (Eastern Hognose Snake). Jones Co: 24.0 km SSE Hamlin on FM 126. 5 May 1968. J. E. Hawkins. (DMNH 4054). Taylor Co: 3.2 km NW Lake Abilene. 15 June 1968. T. L. Hibbitts. (DMNH 4254). Van Zandt Co: 4.8 km ENE Grand Saline. 20 April 1968. J. M. Adkins. (DMNH 4052).

Lampropeltis calligaster calligaster (Prairie Kingsnake). Collin Co: 8.0 km N Wylie on FM 154. 11 July 1979. T. L. Hibbitts. (DMNH 5099). Upshur Co: 4.8 km SE Rhonesboro on FM 49, Maxwell Ranch. 14 March 1971. O. Sanders. (DMNH 2083).

Lampropeltis getulus holbrooki (Speckled Kingsnake). Madison Co: 12.8 km N Madisonville on U.S. 75. 11 April 1976. J. Penner. (DMNH 5155).

Lampropeltis getulus splendida (Desert Kingsnake). Jeff Davis Co: Girl Scout Ranch Rd. 1837 (precise locality not recorded). Collection date unknown. T. L. Hibbitts. (DMNH 4218). Potter Co: Amarillo. 15 June 1971. W. Seifert. (DMNH 4553). Stephens Co: 1.0 km S U.S. 183 on Hubbard Creek Rd. 31 May 1980. T. L. Hibbitts. (DMNH 5256).

Masticophis flagellum testaceous (Western Coachwhip). Ector Co: 8.0 km ENE Penwell. 11 April 1966. L. Foster. (DMNH 3071).

Nerodia erythrogaster flavigaster (Yellowbelly Water Snake). Morris Co: 3.2 km SE Naples on U.S. 67. Collection date unknown. L. Curtis and D. Tinkle. (DMNH 3040). San Jacinto Co: 19.2 km NNW Cleveland, Sam Houston National Forest. 20 April 1974. W. Seifert. (DMNH 1536).

Nerodia rhombifera rhombifera (Diamondback Water Snake). Haskell Co: 8.0 km N Haskell on U.S. 277. 2 April 1966. Kimbrough. (DMNH 4034). Madison Co: Lake Normangee, Normangee. 14 April 1951. W. E. Fosberg and B. E. Hagee. (DMNH 4031-4032). The former record approaches the western limit of the continuous range of *N. r. rhombifera* in Texas (McAllister 1985. Cat. Amer. Aphib. Rept. 376.1-376.4).

Opheodrys aestivus (Rough Green Snake). Limestone Co: Fort Parker State Recreation Area. 16 April 1966. J. Rankin. (DMNH 3910).

Pituophis melanoleucus sayi (Bullsnake). Crockett Co: 16.0 km SSE Ozona on TX 163. 7 June 1965. T. L. Hibbitts. (DMNH 4112). Garza Co: 2.4 km NE Post on FM 651. 17 May 1977. W. Seifert. (DMNH 4653).

Sonora semiannulata (Ground Snake). Clay Co: Lake Arrowhead State Recreation Area. 27 July 1972 and 13 July 1973. W. Seifert. (DMNH 1080, 1076). Garza Co: 13.3 km NE Post on FM 651. 17 May 1977. W. Seifert. (DMNH 4655). Grayson Co: Eisenhower State Recreation Area, Lake Texoma. 11 April 1968. G. Rankin. (DMNH 2847). Starr Co: 4.8 km NW Roma on U.S. 83. 24 May 1971. T. L. Hibbitts. (DMNH 4328).

Tantilla gracilis (Flathead Snake). McCulloch Co: 16.0 km SW Brady on U.S. 190. 16 April 1971. W. Seifert. (DMNH 788).

Tantilla hobartsmithi (Southwestern Blackhead Snake). Reagan Co: 24.0 km SW Big Lake, Ted Harris Ranch. 2 May 1970. T. L. Hibbitts. (DMNH 4291).

Thamnophis marcianus marcianus (Checkered Garter Snake). King Co: 12.9 km S Guthrie on TX 114. 3 May 1980. T. L. Hibbitts. (DMNH 5252).

Thamnophis proximus proximus (Western Ribbon Snake). Hopkins Co: 6.4 km S Sulfur Bluff on FM 69. 18 September 1976. W. Seifert. (DMNH 4597).

Virginia valeriae elegans (Western Earth Snake). Henderson Co: Brownsboro. 15 October 1974. T. L. Hibbitts. (DMNH 4426).

Agkistrodon contortrix contortrix (Southern Copperhead). Limestone Co: 11.3 km SSW Mexia on TX 14, Fort Parker State Recreation Area. 20 April 1966. C. Morley. (DMNH 3889).

Agkistrodon contortrix laticinctus (Broad-banded Copperhead). Clay Co: 12.8 km S Bellevue. 10 September 1954. L. S. Roberts. (DMNH 3897).

Crotalus viridis viridis (Prairie Rattlesnake). Hardeman Co: Quanah on TX 6. 6 April 1972. W. Seifert. (DMNH 1100).

RECENT POPULATION CHANGES

RECENT POPULATION CHANGES provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term population trends (in excess of 20 years) and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this subsection: Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62026, U.S.A.

IMPACT OF EXPANDING HUMAN POPULATIONS ON THE HERPETOFAUNA OF THE VALLEY OF MEXICO

Mexico City and its adjacent urbanized areas now cover almost 2000 km², with some 16 million people seeking a livelihood (Bart 1984; Fernández 1984). The impact of the demographic changes that have taken place in this area over the past 20 years has been immense (Alanis 1978; Guzmán 1979; Bart 1984). Large areas of natural vegetation have been destroyed; soil erosion, regional pollution and drying aquatic habitats have gradually increased, causing profound changes in the local environment. These changes appear to have had a serious impact on the amphibians and reptiles of the Valley of México. In this report we indicate how we perceive the degree of impact these changes are having on the herpetofauna of the Mexico City region.

Based on our field collections, on citations, and on voucher material in scientific collections (Instituto de Biología; Facultad de Ciencias), we have prepared a checklist of the herpetofauna of the Valley of Mexico region. Using this checklist, we assigned each species occurring in the region to one of six categories established by the International Union for Conservation of Nature and Natural Resources (Table 1).

Historically there have been 21 amphibian and 34 reptile species known to have occurred in the Valley of Mexico. Twenty-six of these (47.27% of the total) appear to be adversely affected by human impact. In particular, more than 60% of the amphibians appear to be endangered (Table 2).

We believe that urbanization, regional pollution, and drying aquatic habitats are the main factors that have caused this negative impact on the majority of herpetozoa in the Valley of Mexico.

Indications of acid rain have been reported recently in the Ajusco mountains south of Mexico City (Krupa and Bauer 1982), and its effects on Ajusco plethodontid salamanders are unknown. In addition, we are not sure what influences commercialization and/or human intolerance might be having on various species, especially snakes.

There appear to be some populations that so far have been relatively unaffected by the

Table 1. Human impact on herpetozoan populations from the Valley of Mexico, according to IUCN categories.

PROBABLY EXTINCT

Rana berlandieri ssp., *Kinosternon h. hirtipes, Cnemidophorus gularis* ssp.

IN DANGER OF EXTINCTION

Ambystoma lacustris, Ambystoma mexicanum, Ambystoma tigrinum velascoi, Rhyacosiredon altamiranoi, Rhyacosiredon leorae, Bufo compactilis, Hylactophrine augusti cactorum, Diadophis punctatus dugesi, Rhadinaea laureata.

VULNERABLE

Chiropterotriton chiropterus, Pseudoeurycea leprosa, Pseudoeurycea altamontana, Pseudoeurycea b. belli, Pseudoeurycea c. cephalica, Hyla arenicolor, Hyla eximia, Thamnophis dorsalis cyclides, Thamnophis e. eques, Thamnophis m. melanogaster, Thamnophis scalaris scaliger, Phrynosoma o. orbiculare, Crotalus polystictus, Crotalus molossus nigrescens, Crotalus triseriatus aquilus.

RARE

Chiropterotriton dimidiatus, Hyla robertsorum, Abronia taeniata taeniata.

INDETERMINATE

Tomodactylus fuscus, Tomodactylus grandis, Rana montezumai, Crotalus t. triseriatus, Crotalus transversus, Sistrurus ravus, Salvadora bairdi, Toluca l. lineata, Conopsis biserialis, Conopsis n. nasus, Pituophis d. deppei, Eumeces l. lynxe.

OUT OF DANGER

Scaphiopus hammondi multiplicatus, Hyla plicata, Eumeces copei, Eumeces b. brevirostris, Barisia i. imbricata, Sceloporus a. aeneus, Sceloporus aeneus bicanthalis, Sceloporus t. torquatus, Sceloporus s. spinosus, Sceloporus grammicus microlepidotus, Sceloporus s. scalaris, Sceloporus m. mucronatur, Storeria storerioides.

Table 2. Species percentage (amphibians and reptiles) affected, in relation to total number of taxa

Taxa	Species Number	Percentage (%)				
		TOTESP	TOTEAF	TOTEAN	TOTURO	
Amphibia	14+	25.45	66.66+	—	—	
Anura	5	9.09	23.80+	45.45+	—	
Urodela	9	14.54+	38.09+	—	66.66+	
		TOTESP	**TOTREP**	**TOTECH**	**TOTELA**	**TOTESE**
Reptilia	12+	21.81+	35.29+	—	—	—
Chelonia	1	1.80	2.94	100+	—	—
Lacertilia	2	3.63	5.88	—	15.38	—
Serpentes	9	16.36+	26.47+	—	—	52.94+

+Taxa most affected

- TOTESP = in relation to total number of herpetological species
TOTEAF = in relation to total species number of Amphibia
TOTEAN = in relation to total species number of Anura
TOTURO = in relation to total species number of Urodela
TOTREP = in relation to total species number of Reptilia
TOTECH = in relation to total species number of Chelonia
TOTELA = in relation to total species number of Lacertilia
TOTESE = in relation to total species number of Serpentes

human population expansion. These are (with possible explanation for continued existence in parentheses): *Scaphiopus h. multiplicatus* (high reproductive capacity), *Sceloporus grammicus* (adaptation to urbanized areas), *Eumeces copei, E. brevirostris, Sceloporus aeneus, Storeria storerioides* and *Hyla plicata* (mainly found in mountainous terrain which is not yet heavily populated), and *Sceloporus scalaris* and *S. spinosus* (distributed in the northeastern Valley of Mexico, which is still unurbanized).

If the chaotic growth of Mexico City is not brought under some control, many more herpetological populations are doomed to decimation or extinction. We look to the Urban Reordination and Ecological Conservation Program and the Agricultural Development Coordination Commission, both within the Federal District, to begin to resolve some of these great problems.

ACKNOWLEDGMENTS

We thank the following persons for their constructive criticisms in reviewing this paper and/or for their logistic aid: Dr. Ralph W. Axtell, Dr. Gustavo Casas A., M.C. Gustavo Aguirre, M.C. Jorge Nocedal. M.C. Ernesto Aguirre, Dr. Fermín Rivera, M.C. Gabriel Camarena and Dr. Elsa Calleja.

BOOK REVIEWS

A Guide to the Identification of Amphibians and Reptiles of the West Indies Exclusive of Hispaniola, by Albert Schwartz and Robert W. Henderson. 1985. Milwaukee Public Museum. 1-165 pp., 2 maps, 87 figures, 19 pls., wrappers. $29.95.

In his pioneering work on zoogeography, Alfred Russell Wallace (1876) wrote, "The West Indies have long been isolated . . . their separation from the continent took place at a remote period, and they have since broken up into numerous islands, which have probably undergone much submergence in recent times. This has led to that poverty of the higher forms of life, combined with the remarkable specialty, which now characterizes them . . . " Thomas Barbour's (1914) first checklist to the amphibians and reptiles of the West Indies listed 35 amphibian species and 250 reptile species. Twenty-three years later Barbour (1937) recognized 83 amphibian and 286 reptile species. Cochran (1941) reported 33 amphibian and 74 reptile species from Hispaniola. Forty-four years later Henderson and Schwartz (1984) listed 58 amphibian and 130 reptile species from Hispaniola, and since that publication several new taxa have been described from that island. In the volume under review, Schwartz and Henderson list 22 families holding 67 genera represented by 373 species of amphibians and reptiles. Thus, Wallace's impoverished islands have been shown to have a rich herpetofauna that rivals that of any on the South American mainland. A crude, but expedient, way to compare the faunas would be to look at the number of species per square mile. Considering Ecuador, Miyata (1982) lists 344 amphibian and 334 reptile species from that country of 109,483 square miles, or 0.0061 species/square mile. The West Indies, exclusive of Hispaniola, has a land surface of about 61,720 square miles and 0.0060 species/square mile. For comparison the states of Illinois and Florida have 0.001 and 0.002 species/square mile, respectively.

Now, thanks to Schwartz and Henderson, the zoologist traveling in the West Indies can carry two volumes (this one and Henderson and Schwartz, 1984) and identify most of the members of this diverse herpetofauna. The most useful part of this volume will be the 49 keys to orders, genera and species. To facilitate easy use there are separate keys to species in large genera by island; where species occur on more than one major island it is noted in the key; and wherever genera have less than 15 Antillean species they are all listed in a single key. The keys will be invaluable for those of us who have tried to identify an *Anolis* or *Eleutherodactylus* that a friend captured on a cruise, particularly when the friend can't remember if the specimen was found on St. Croix, St. Thomas or Guadeloupe.

Following the keys are checklists of species that include subspecific names applica-

ble to West Indian populations, a Key Literature section and a coded distribution for that species. The Key Literature sections may prove extremely useful for those who want more than a name; these sections are a guide to the non-taxonomic literature for each species. Key Literature sections have greatly increased the Literature Cited - Bibliography to more than 1000 items on 42 pages.The coded distributions are helpful, but they cannot match those in Schwartz and Thomas (1975) and Schwartz, Thomas and Ober (1978), nor are they meant to. The species lists and keys are exceptionally complete, including species that have been introduced by man or chance. For example, the key to *Crocodylus* includes *C. intermedius*. A single specimen was reported by Barbour (1914) to have reached Grenada in September of 1910 and no other sightings have been reported north of Trinidad since then (Medem 1983).

The watercolor plates of *Anolis, Chamaeleolis* and *Chamaelinorops* (pls. I-XI) by David C. Leber are magnificent and add considerable value to the volume, but they are undoubtedly responsible for the rather hefty price. Oddly, plates VI and VII are of Hispaniola taxa despite the fact that the volume is exclusive of that island. They would be more appropriately placed in the 1984 volume, but one of the authors (RWH) told this reviewer that the second volume was not planned until after the Hispaniolan volume was nearly completed. Nevertheless, it is worth the minor annoyance to have 104 taxa represented in such colorful detail. Following the anoline watercolors are eight color photographs of snakes and 36 black and white photographs of habitat and animals; the photographs are usually of good quality. Island species lists and a glossary precede the Literature Cited -Bibliography.

There are some problems, albeit minor ones. The keys are designed for live or freshly preserved material with patterns and colors intact, thus the identification of old, faded museum material becomes difficult. The key to the Lesser Antillean *Anolis* (p. 43) requires that specimens of both sexes be available to pass couplet number 5. Three items in the Literature Cited lack dates: Dixon and Huey, p. 128; Drewry and Jones, p. 129; and Lazell, p. 142. Also in the Literature Cited, Roughgarden (1979) lacks pagination. The Key Literature Section for *Anolis roosevelti* (p. 48) is given as, "Williams, 1962," however there are two papers by Williams 1962 in the Literature Cited (a and b), and which one refers to *A. roosevelti* is unclear based on titles alone. The use of *Rana utricularia* instead of *Rana sphenocephala* (p. 24) is questionable. Despite the fact that *utricularia* is an older name than *sphenocephala* the latter has received wider usage - see the comment by Hillis (p. 515) in Frost (1985). If the publisher reaches a point where this volume and Henderson and Schwartz (1984) need to be reissued, combining the two into one volume would be highly advantageous.

Professional and serious amateur herpetologists will want this book for its highly usable keys and extensive bibliography. However, the excellent artwork will be a major factor in making the volume more appealing to a wider audience.

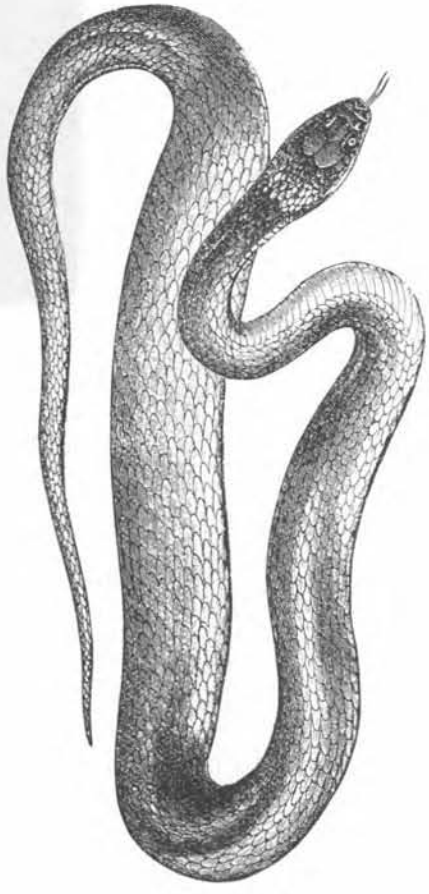
JOHN C. MURPHY
403 N. Division Street
Plainfield, Illinois 60544, U.S.A.



A Field Guide to the Lizards of Western Ghats, by T. S. N. Murthy. Records of the Zoological Survey of India, Miscellaneous Publ. Occas. Pap. no. 72, pp. 1-51, 1985. Rs. 40, $8.50.

This slim pamphlet appearing in the series of the Zoological Survey is intended to provide a review of the lizard fauna of the Western Ghats, the interesting mountain range that separates Kerala from Tamil Nadu and extends north parallel to the west coast of India. The montane fauna of Southern India is rich and remains poorly studied. The preface refers to the need for further study and the text provides brief descriptions relying upon the reports of Malcolm Smith, amplified by data from the scattering of papers which have appeared thereafter. The book is illustrated with photographs of assorted museum specimens, some deriving from the British Museum (N.H.). There is a general map, a key and a guide to scale characters. Sixty-three species are noted.

I am of two minds in evaluating this pamphlet. On the one hand, this brochure can serve to raise the consciousness of the local public. This is important and the aim is similar to, though not as extensive or as well produced as, that of Daniels' REPTILES OF INDIA, and somewhat more technical than Whitaker's guide to the snakes of India. However, the present pamphlet seems not to have been addressed to this audience but to a more technical one, and here, it fails. It fails because it does not provide even the minimum level of documentation required in science, namely that the observations and comments be repeatable and hence subject to test.

Neither the locality and ranges given in the individual accounts, nor the photographs at the back of the volume make reference to actual specimens or to museum numbers which might permit one to check attribution or locality. Consequently, there is no built-in mechanism of self correction. One must "accept the voice of authority," and cannot hope for progress by successive approximation. We need better collections, but also we need reports with adequate documentation. Reports about animals should tell us where these were collected and where (and under what numbers) they are deposited. This minimal addition permits other workers to check, and hopefully to improve, the state of our knowledge.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1985

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

1986 HL-SSAR MEETING

The March issue of Herp. Review will contain a detailed outline of the events scheduled for the annual meeting of the Herpetologists' League and the Society for the Study of Amphibians and Reptiles on 10-15 August, 1986 at Southwest Missouri State University. Scheduled events include the HL Distinguished Speaker, paper and poster sessions, a symposium on "The Behavioral Ecology of Salamanders" chaired by Robert Jaeger and Kiisa Nishikawa, a workshop on "Regional Societies in Public Education" sponsored by the Regional Herpetological Society Liaison Committee, a symposium-workshop on snake venom poisoning sponsored by the Zoo Liaison Committee, the annual auction, another Dennis-Juterbock slide show, a herpetofaunal display, a banquet, a B-B-Q supper, a social (or two), and a float trip on the Niangua River.

Plans are being finalized by International Expeditions, Inc. for reduced air fares to Springfield.

EXHIBITORS WANTED FOR 1986 JOINT HL-SSAR MEETING

The local committee for the 1986 HL-SSAR meeting in Springfield, Missouri is in the process of contacting possible exhibitors for the meeting. Any individual or organization is welcome to display herpetologically-oriented material (except live animals). The following information may be useful to potential exhibitors.

Registrants: Biologists, college professors, zoo and museum personnel, state and federal wildlife officials, graduate students in biology and serious lay persons with interests in amphibians and reptiles.

Previous Exhibitors: Publishers, used-book companies, biological supply companies, manufacturers of animal collecting and housing equipment, artists (with animal themes), tee-shirt sellers, and travel services.

Cost: $125 for each table (approx. 4x6 feet). Artists who sell materials created by themselves will be charged $125 or the equivalent in donated art or crafts; such persons are expected to be engaged actively in their work at the exhibit area.

For exhibit application, or further information, contact:

Ruth Zantzinger
2108 Cherry Street
Philadelphia, Pennsylvania 19103, U.S.A.
(215) 557-0182

SSAR COMMITTEES FOR 1985-1986

Following the Tampa meeting, President Pisani appointed the following committees and coordinators for the current year to report to the Board at the Springfield meeting in 1986. Individuals with important matters pertaining to the activities of Society committees should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of *Herpetological Review*.

Conservation: William S. Brown (Ch), John L. Behler, M.R.K. Lambert, Paul E. Moler, and Patricia Riexinger.

Grants-in-Herpetology: Thomas H. Fritts (Ch), Robert Bader, C. Kenneth Dodd, Arthur C. Echternacht, Darrel Frost, Susan Schafer, and Michael V. Plummer.

Kennedy Student Award: J. Eric Juterbock (Ch), Robert E. Gatten, Ken R. Marion, John S. Mecham, and Laurie J. Vitt.

Long-range Planning: James L. Christiansen (Ch), Ralph Axtell, Carl Gans, James S. Jacob, Henri C. Seibert, and Douglas H. Taylor.

Meetings (SSAR/HL): Henry R. Mushinsky (Ch), Ray E. Ashton, Victor H. Hutchison, and James S. Jacob.

Nominating: Hugh R. Quinn (Ch), Kraig Adler, Douglas H. Taylor, Lynne D. Houck, and James S. Jacob.

Regional Society Liaison: Ray E. Ashton (Ch), Martin J. Rosenberg, Thomas Vermersch, John E. Simmons, Terry Hibbitts, Harold DeLisle, and Jeff Whipple.

Zoo Liaison: Richard A. Sajdak (Ch), Dale Belcher, Ronald Goellner, William Lamar, Joseph Laszlo, and Ruth Zantzinger.

Common and Scientific Names Coordinator: Joseph T. Collins.

Translations Coordinator: Robert D. Aldridge.

JAMES S. JACOB
SSAR Secretary ●

SSAR BALLOT FOUL-UP

All Society members should have received a ballot, ballot envelope and dues envelope in the September issue of *Herpetological Review*. Incorrect application of mailing labels after the issues were delivered to the mailing house, however, resulted in many members receiving copies of *HR* which lacked these important inserts. An attempt to remedy this situation by mailing separate ballots to all members was confounded by the failure to include the elector's name and address on the new ballot. Although a number of these secondary ballots were returned to the University of Kansas (the return address on the envelope), we assure members that their ballots have been forwarded to the elector and that their votes have been counted.

In the event that your September *HR* also lacked a dues envelope, we reprint the dues information here and ask that you submit your renewal dues as soon as possible.

We apologize for these inconveniences and assure you that steps are being taken to avoid similar occurrences in the future. ●

Send dues to:
The Society for the Study of
Amphibians and Reptiles
Dr. Henri C. Seibert, SSAR Treasurer
Department of Zoology
Ohio University
Athens, Ohio 45701, USA

***NOTE:* Prompt payment of dues and subscriptions saves your Society time and money. SSAR publications are sent only to active members and subscribers. Please pay by 31 December to guarantee uninterrupted benefits.**

***SSAR GRANTS-IN-HERPETOLOGY**

The Grants-In-Herpetology program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. SSAR is establishing an endowment to help support the program and requests your support in this effort. All contributions are tax deductible.

Payment Method: Check or Money Order enclosed ☐ MasterCard ☐ VISA ☐
A receipt will be sent only upon request.

Credit Card Number: _____ Expiration Date: _____

NOTE: A 3% bank charge will be added to your credit card account. Your signature authorizes SSAR to debit your MasterCard or VISA account.

Signature _____

28TH ANNUAL MEETING HELD AT UNIVERSITY OF SOUTH FLORIDA

The 1985 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League in Tampa, Florida, during 3-9 August. Local Committee chairman Henry R. Mushinsky hosted an international gathering of herpetologists totaling 406 members and guests on the campus of the University of South Florida.

SSAR BOARD OF DIRECTORS MEETING

The annual meeting of the Board was held on Sunday, 3 August, under the chairmanship of SSAR President George Pisani. All Board members were present plus other officers, editors, committee chairs, and several visitors. The Board met for 5 hours and 43 minutes (a record for the shortest Board meeting) and discussed annual reports submitted by each Society officer, editor, committee, and coordinator plus a number of other items. In addition to the decisions announced at the business meeting on 5 August (see below), the Board took the following actions: (1) SSAR will play only a background role in the planning for the 1986 joint Annual Meeting since the Herpetologists' League will be celebrating the 50th anniversary of the publication of *Herpetologica*. (2) The Society will sponsor the auction, a conference organized by the Regional Society Liaison Committee, and a symposium organized by the Zoo Liaison Committee at the 1986 Annual Meeting and will cosponsor a symposium on "Behavioral Ecology of Salamanders" to be organized by Robert Jaeger. (3) The policy of assessing a late fee for failure to pay dues on time was rescinded. (4) The Board announced the availability of a pamphlet on "Herpetology as a Career." It is available from the Publications Secretary, at no charge for single copies.

CONFERENCES AND WORKSHOP

The SSAR Zoo Liaison Committee sponsored a conference on "Ecology and Reproduction of West Indian Herpetofauna." The conference, consisting of eight presentations, was organized and chaired by Peter J. Tolson.

The 9th Annual Regional Herpetological Society Conference was sponsored by the SSAR Regional Society Liaison Committee chaired by Terry Hibbitts. Eight papers were presented which dealt with the topic of the Conference, "Methods to Enhance the Regional Societies."

A workshop on the status of *Gopherus polyphemus* was also held during the Tampa meetings. Six presentations and a field trip to the University of South Florida Ecological Research Area dealt with the ecology, reproduction, management, and conservation of *Gopherus* in the southeastern United States. The workshop was organized by the Gopher Tortoise Council, Florida State Museum.

SPECIAL ACTIVITIES, EXHIBITS, AND SOCIAL EVENTS

The Local Committee organized an outstanding series of activities which enhanced the meeting tremendously. An opening night social provided an opportunity to greet old and new friends. A barbecue dinner and open house was held on Monday night at the Museum of Science and Industry. On Tuesday evening, there was an excellent tour of Busch Gardens which was attended by 130 people.

A well-attended slide presentation of "Herps of the Dallas Zoo" was given by Jim Murphy on Tuesday night using slides taken by David Barker. David Dennis and Eric Juterbock presented their magnificent multimedia show on "Amphibians of the Appalachians" on Wednesday night. They also showed an updated version of the SSAR sponsored multi-media slide show "Herpetologists: Past and Present." Following these acclaimed presentations, the traditional social and auction was held. Due to the generous support of our members, the auction was again successful and provided financial support for meeting expenses. A sold out closing-night dinner was held on Thursday which was attended by 200 people. The event was personally catered by Ernie Liner using his famous cajun recipes for alligator, turtle, frog, and catfish.

BUSINESS MEETING

A. Call to Order

President George Pisani called the 1985 business meeting of the Society to order at 1700 hr in room 1201 of the USF Busi-

ness Administration Building.

B. Report of the Secretary

Secretary James Jacob summarized actions taken by the SSAR Board of Directors since the 1984 annual meeting. The Board approved installing microcomputers in the offices of the Secretary, Treasurer, and Publications Secretary in order to more efficiently handle the business of the Society. The Board also approved a policy on bequests. The Internal Revenue Service recognizes SSAR as a publicly supported organization eligible to receive income-tax deductible donations. Members were encouraged to remember the Society in their wills.

The following resolution supporting the establishment of a national biological survey was approved by the Board and sent to the National Biological Survey Planning Committee:

Whereas faunal and floral surveys, and the production of species atlases, catalogues and identification manuals for the many economically important groups of organisms are needed in the United States of America to provide basic scientific information on diversity, distribution and the factors affecting these; and,

Whereas knowledge of the effects of habitat alteration on organismic diversity and distribution is increasingly critical; and,

Whereas the number of presently undescribed organisms globally has been estimated in excess of one million and the number of these in this country is felt to be significant; and,

Whereas there presently is no national direction or coordination of studies addressing these needs; and,

Whereas twenty-two professional societies and state biological surveys have endorsed in principle the establishment of a National Biological Survey;

Therefore, Be it Resolved that the Society for the Study of Amphibians and Reptiles join these organizations in the endorsement of the establishment of a National Biological Survey.

C. Report of the Treasurer

Treasurer Henri Seibert announced that the Society is in good financial shape. A dues increase will not be necessary in 1986. Our membership and subscribers appear to have stabilized at approximately 2,300. The Board approved a $98,000 budget for 1986, of which $50,480 is designated for publication of the *Journal of Herpetology*.

D. Editors' Reports

1. *Journal of Herpetology*

In the absence of Rodolfo Ruibal, Editor of the *Journal of Herpetology*, Associate Editor Paul Hertz announced that the Journal's editorial process had been restructured during 1985. The Editorial Board was appointed which consists of Paul Hertz, Samuel Sweet, Thomas Jenssen, and Lis Olesen Larsen. The responsibility for reviewing manuscripts is now shared by the Editor and Associate Editors. This procedure should speed the processing of manuscripts. Hertz noted that 190 manuscripts were received last year, of which approximately 50% were accepted. Fifty-three of the 190 manuscripts were from authors outside the United States.

2. *Herpetological Review*

Martin Rosenberg, Editor of *Herpetological Review*, announced that the Board had approved the establishment of a subscription category for *Herpetological Review* which will cost $10 per year. The availability of *Herpetological Review* on a subscription basis should have wide appeal among the individuals who belong to regional herpetological societies but who do not currently belong to the Society. Rosenberg noted that an extensive advertising campaign would be undertaken.

3. *Recent Herpetological Literature*

George Pisani, Editor of *Recent Herpetological Literature*, announced that the series had been discontinued due to loss of computer support previously arranged through Allen Press and the Association of Systematics Collections. Ways by which the series can be continued are being pursued. The possibility of associating with *Zoological Record* was discussed. Victor Hutchison commented that with the expansion of various on-line literature retrieval services, a hard copy format of *Recent Herpetological Literature* might become extinct within a few years.

4. *Herpetological Circulars*

President Pisani announced that Joseph Mitchell's manuscript entitled "Cannibalism and Related Behavior in Reptiles" will appear next year as a Circular. John Simmons' manuscript on "Herpetological Collecting and Collections Management" is being reviewed and will appear in the near future.

F. Committee Reports

1. Conservation

President Pisani announced that the Board of Directors approved two resolutions and a position paper presented by the Conservation Committee. In response to a request from Mary Anderson of the United States Humane Society, the following resolution was approved:

Whereas millions of hatchling turtles produced on breeding farms in the southeastern United States are being exported to Europe, the Far East and other parts of the world for the pet trade; and

Whereas these turtles are an important route for the transmission of salmonellosis; and

Whereas the trade requires the taking of an estimated 100,000 adult turtles out of the wild every year to replace breeding stock which has perished; and

Whereas the pet turtle industry is continuing efforts to get the existing domestic ban on the sale of hatchlings lifted, thereby opening up a market for many additional millions of hatchlings, thus necessitating severe exploitation of wild populations for breeding stock,

Therefore, Be it Resolved that SSAR goes on record as opposed to the commercial exploitation of chelonians for pet industry purposes.

In response to a request from Allan Puskar of Wellsboro, Pennsylvania, to the Conservation Committee, the Board of Directors approved the following resolution to address problems created by organized snake hunts and sacking contests in Pennsylvania:

Be it Resolved that SSAR is on record as being opposed to organized commercial snake hunts, sacking contests, and related activities that are judged by professional herpetologists to constitute inhumane treatment to the snakes involved and are detrimental to their populations.

The Conservation Committee received a request from Deputy Commissioner Dennis DeCarli of the Department of Environmental Protection of the State of Connecticut regarding conflicts between homeowners and timber rattlesnakes in Glastonbury, Connecticut. An area was developed on a timber rattlesnake den and the homeowners are now requesting that the snakes be either destroyed or moved. The State of Connecticut has requested recently passed legislation protecting *Crotalus horridus*. Mr. DeCarli asked for a statement from SSAR recommending how the situation should be handled. The Board approved a position paper prepared by the Committee which advises the State that "... total eradication is not warranted (nor legal) and relocation is not feasible on both biological and practical grounds. Problems between this species and humans could be best approached through the removal of offending snakes on an individual basis."

2. Grants-in-Herpetology

James Bacon, Chairman of the Grants-in-Herpetology Committee, announced that he received 37 applications, of which 28 met the criteria for review. The following grants were awarded for 1985:

Conservation Research: Lee A. Fitzgerald, Department of Biology, Museum of Southwestern Biology, University of New Mexico, "Reproductive Biology and Demography of *Caiman yacare* and *Caiman latirostris* in Paraguay," Awarded $400; **Graduate Student Research:** Frances J. Irish, Harvard University, "The Evolution of Tooth Replacement Patterns in Snakes: Mechanisms and Implications," Awarded $400, and George R. Cline, Oklahoma State University, "Gene Flow Between Two Forms of The Gray Treefrog, *Hyla chrysoscelis*, in Geographic Areas of Contact," Awarded $400; **Regional Society Research:** Harold F. DeLisle, The Southwestern Herpetologists Society, "The Present Status of the Herpetofauna of the Santa Monica Mountains," Awarded $350; **Field Work:** Douglas E. Ruby, Department of Biological Sciences, Drexel University, "Variation in Territorial Behavior in the Iguanid Lizard, *Sceloporus jarrovi*," Awarded $225, and Chris T. McAllister, Renal-Metabolic Laboratory, Veterans Administration Medical Center, Dallas, Texas, "The Role of Environmental Constancy on Oxygen Consumption and Thermal Sensitivity in Relict Population of

Hemidactyline Plethodontid Salamanders," Awarded $225; **Zoo Research:** Victoria A. Teubner, University of Toledo, "Endocrine and Behavioral Aspects of Reproduction in the Haitian Boa *(Epicrates striatus)*," Awarded $400.

Abstracts of these proposals were published in *Herpetological Review (16(3))*. Bacon also announced that the granting cycle will be changed so that awards can be made earlier in the year. Proposals sent to the Committee Chair will now have to be postmarked by 31 January. Awards will be announced by 15 March in order to make funds available for use during the summer. The new deadlines were advertised in the September issue *Herpetological Review*. A new form also will be prepared for applicants to use.

3. Kennedy Student Award

President Pisani announced that the Kennedy Student Award Committee, chaired by Eric Juterbock, judged that the best student paper published in volume 18 of the *Journal of Herpetology* was authored by Robert L. Seib of the University of California at Berkeley. The paper was entitled: "Prey Use in Three Syntopic Neotropical Racers" and appeared on pages 412-420.

4. Nominating

President Pisani announced that the Board of Directors had approved the recommendation of the Nominating Committee, chaired by Douglas Taylor. The following members were nominated to stand for election to SSAR offices for 1986. **President:** Norman J. Scott (U.S. Fish and Wildlife Service, University of New Mexico) and Linda R. Maxson (University of Illinois); **Secretary:** James S. Jacob (Glendale College) unopposed; **Treasurer:** Henri C. Seibert (Ohio University) unopposed; **Director (General Membership):** Lynne D. Houck (University of Chicago) and Victor H. Hutchison (University of Oklahoma); **Director (Zoo Membership):** Dale Belcher (Rio Grande Zoo, Albuquerque, NM) and William W. Lamar (Caldwell Zoo, Tyler, TX).

President Pisani opened the floor for additional nominations. None was made and J. T. Collins moved that the nominations close. James Murphy seconded and the motion passed unanimously. Ballots were mailed with the September issue of *Herpetological Review*. David Grow (Oklahoma City Zoo) will serve as Elector. Ballots must be returned to him by 15 December 1985.

5. Meetings

President Pisani announced that the Board of Directors has received and approved an invitation from Southwest Missouri State University (SMSU) in Springfield to host the 1986 annual meeting.

6. 1986 Local Committee

President Pisani introduced Robert Wilkinson, Co-Chairman of the 1986 Local Committee. Wilkinson announced that Don Moll will serve as the other Co-Chairman. Wilkinson then showed slides of the SMSU campus, pointing out that the University has an enrollment of approximately 15,000 students, of which about 2,000 are graduate students, and occupies a 125 acre site in Springfield, Missouri. Springfield is a community of 150,000 people, the third largest city in the state, and is located on the western edge of the Ozark plateau. It is served by Ozark and Frontier Airlines. The Science Building will be used as the actual meeting site. Campus housing will be available at a rate of $11 per person per night. Facilities will consist of apartments which have two or three bedrooms and one bathroom. Preregistration will be no higher than it was for the 1985 Tampa meeting. The 1986 annual meeting will be held during 10-15 August.

7. Transfer of Society Gavel

President Pisani recognized President-elect Sherman Minton and presented him with the SSAR gavel.

H. Adjournment

President-elect Minton asked if anyone had any further business. There being none, James Murphy moved, and Victor Hutchison seconded, that the meeting be adjourned. The motion passed unanimously, and President-elect Minton declared the meeting closed at 1738 hr.

RESOLUTIONS

The following resolutions were presented at the closing night dinner by SSAR President George Pisani:

1. *Whereas* the following persons have generously contributed their time to the Society for the Study of Amphibians and Reptiles in their several capacities; and

   Whereas their appointments were relinquished during 1984; and

   Whereas SSAR hopes to entrap these and others to perform various functions in future years

   Therefore, Be it Resolved that the Society for the Study of Amphibians and Reptiles extends its sincerest thanks to the following persons: Carl Gans, President; Ralph W. Axtell, Immediate Past President; Thomas H. Fritts and Norman J. Scott, Jr., Directors; George R. Pisani, Managing Editor of *Herpetological Review;* Linda E. Maxson, Chair of Grants-in-Herpetology Committee; Diane M. Secoy, Chair of Nominating Committee; and Lynne D. Houck, Chair of Joint Meeting Committee.

2. *Whereas* the University of South Florida has most generously invited the Society for the Study of Amphibians and Reptiles and the Herpetologists' League to defile its campus; and

   Whereas more than the usual number of lithe, suntanned persons have been available for admiration all across campus; and

   Whereas the University of South Florida has been only the second host institution of an SSAR/HL meeting to have the good grace to schedule a concurrent cheerleader camp; and

   Whereas officials of the University have contributed generously to meeting finances

   Therefore, Be it Resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League extend its thanks to the University of South Florida for serving as meeting host.

3. *Whereas* Henry Mushinsky, ably assisted by Mary Ann Solic and numerous others pressed into temporary (we assume) servitude have worked their anal plates off to make certain that this meeting was well organized and executed; and

   Whereas they have succeeded admirably despite failing to feed Pisani to the lions at Busch Gardens

   Therefore, Be it Resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League extend sincerest thanks and appreciation to Henry Mushinsky, Mary Ann Solic and their unnamed band of stalwarts for their considerable effort.

4. *Whereas* the distances traversed by meeting participants have done much to stimulate good cardiovascular fitness; and

   Whereas the Tampa mosquito squadrons and chigger patrols have done their best to relieve participants of excess blood; and

Whereas the numbering system in the Village has done much to stimulate walking tours

Therefore, Be it Resolved that SSAR and HL recommend that future USF meetings be cosponsored by the American Medical Association's Council on Cardiovascular Fitness.

5. *Whereas* it is apparent that herpetologists have a consuming interest in their field; and

Whereas they may be the start of a meeting tradition to be superseded by such delights as python parmesan and anolis almondine; and

Whereas Ernie Liner has worked long and hard to prepare this dinner

Therefore, Be it Resolved that SSAR commends Ernie for his efforts and bestows upon him the title of Official SSAR Chef.

PAPERS AND POSTERS PRESENTED

One hundred and thirty-six oral papers were presented during the five-day meeting in three concurrent sessions. In addition to the oral presentations, 16 posters were displayed during the meeting. Titles are presented below.

JOINT OPENING SESSION

CARL GANS, University of Michigan. Herpetologists' League Distinguished Lecture:
Limbless locomotion: Status and prospects of our understanding.

STEVEN P. CHRISTMAN, U.S. Fish and Wildlife Service.
Florida focus: Natural diversity and progress — amphibians and reptiles in Florida.

CONTRIBUTED PAPER SESSIONS

SALAMANDER ECOLOGY

CHAIRS: ERIC J JUTERBOCK, RICHARD C. BRUCE

POLGAR, L. W., Southern Illinois University at Carbondale.
Brine shrimp nauplius bioassay for skin toxins of *Notophthalmus viridescens* efts.

LUE, K. Y., D. S. Chuang, S. H. Chen and Y. S Lue, National Taiwan Normal University. Republic Of China
The antipredator behavior of Formosan salamanders, *Hynobius formosanus.*

ETHERIDGE K., University of Florida.
The energetics of estivation in trenid salamanders *(Siren lacertina* and *Pseudobranchus striatus).*

HOLOMUZKI, J. R., Arizona State University.
Ontogenetic variation in diet of larval tiger salamanders, *Ambystoma tigrinum nebulosum.*

BRUCE, R. C., Western Carolina University and Highlands Biological Station.
Upstream and downstream movements of *Eurycea bislineata* and other salamanders.

CHEN, S. H. and K. Y. Lue, National Taiwan Normal University. Republic of China
The population study of *Hynobius formosanus.*

KERN, W. H., JR., Indiana State University.
The use of baited hoop nets to capture hellbenders, *Cryptobranchus alleganiensis,* and its effect on food habits analysis.

KEEN, W. H. and R. W. Reed, State University of New York, College at Cortland.
Differences in use of cover site types by sexes of *Desmognathus monticola.*

JUTERBOCK, J. E., The Ohio State University at Lima.
Nesting phenology of the dusky salamander *Desmognathus fuscus.*

BOGART, J. P. and L. E. Licht, University of Guelph York University.
Sex in parthenogenetic all-female salamanders of the genus *Ambystoma.*

SEVER, D. M., Saint Mary's College.
Disparate sexual variation in *Gyrinophilus, Pseudotriton,* and *Stereochilus.*

SALAMANDER GROWTH AND DEVELOPMENT

CHAIR: RICHARD SEIGEL

REILLY, S. M., Southern Illinois University at Carbondale.
The ecological morphology of neoteny in *Notophthalmus viridescens* and *Ambystoma talpoideum.*

ZALISKO, E. J., Washington State University.
Fate of unused sperm in post-breeding male *Ambystoma macrodactylum columbianum.*

HUTCHERSON, J. and R. Wilkinson, Southwest Missouri State University.
Growth and metamorphosis of ringed salamanders.

HALLIDAY, T. R., Open University, England.
Reproductive cycle and mating competition in the smooth newt, *Triturus vulgaris.*

REAGAN, N. L., Western Carolina University.
Larval life history studies of the *Eurycea bislineata wilderae* complex in Western North Carolina with especial reference to altitudinal variation.

SALAMANDER TAXONOMY

CHAIR: DAVID M. SEVER

JONES, T. R. and J. P. Collins, Arizona State University.
An electrophoretic analysis of Southeastern Arizona *Ambystoma tigrinum:* Hypothesized taxonomic affinities and biogeography.

HAAS, C. A., University of Maryland, College Park.
Geographic protein variation in *Plethodon cinereus* from the southern part of its range.

LOWCOCK, L.A., University of Guelph.
Electrophoretic evidence for multiple origins of triploid forms in the *Ambystoma jeffersonianum* complex.

KEZER, J. and P. Moler, University of Oregon and Florida Game and Fresh Water Fish Commission.
Chromosome variation in *Pseudobranchus.*

ANURAN ECOLOGY

CHAIRS: EDMUND D. BRODIE, CRAIG NELSON

PECHMANN, J.H.K. and R. D. Semlitsch, Savannah River Ecology Laboratory.
Diel activity patterns in the breeding migrations of four winter-breeding anurans.

LONDOS, P. L., University of Guelph.
Time course of locomotory adaptability in the toad, *Bufo woodhousei woodhousei,* as influenced by temperature and photoperiod.

NELSON, C. E., Indiana University.
Do tadpoles die for their siblings?

HEWS, D. K., Oregon State University.
Adaptive significance of larval toad alarm reaction.

VANDERBURGH, D. J., University of Guelph, Canada.
The effect of larval habitat desiccation on toad (*Bufo* spp.) reproductive effort.

HESS, J. B., Central Missouri State University.
A method of quantifying colors.

DONNELLY, M. A., University of Miami.
Feeding patterns of the strawberry poison-dart frog, *Dendrobates pumilio.*

BRODIE, E. D. JR. and D. R. Formanowicz, Jr., The University of Texas at Arlington.
Unpalatability in the evolution of aggregation: Protection of palatable individuals.

ZIMMERMAN, B. L. and J. P. Bogart, World Wildlife Fund — US, Washington, D. C.
Specificity of breeding habitat in four little known Central Amazonian forest frog species.

GODWIN, J. C., Department of Zoology-Entomology, Auburn University. **Extrinsic factors influencing the calling of *Hyla andersoni.***

ANURAN TAXONOMY

CHAIR: PAUL E. MOLER

HUTCHINSON, M. N. and L. R. Maxson, University of Illinois at Urbana-Champaign.
Albumin evolution, paraphyly and the relationships of the Australian frog *Megistolotis lignarius* (Anura: Limnodynastinae).

ANDERSON, K., New York University.
Effect of restriction enzymes on C-banding patterns in hylid chromosomes.

DRYSDALE, T. A., University of Guelph.
Eye specific isozyme effects in various Anura.

MAXSON, R. D. and L. R. Maxson, University of Illinois at Urbana-Champaign.
The phylogenetic basis of micro-complement fixation.

MAXSON, L. R. and R. Ruibal, University of Illinois-UC and University of California, Riverside.
Relationships of frogs in the Leptodactylid subfamily Ceratophryinae.

MOLER, P. E., Florida Game and Fresh Water Fish Commission.
An introduction to *Rana okaloosae,* a new species of Florida frog.

HAYES, M. P., University of Miami.
Vocal sac variation within *Rana aurora* (Ranidae): How many historical units?

LAMB, T., Savannah River Ecology Laboratory.
Directional introgression of mitochondrial DNA in a hybrid population of treefrogs: The influence of mating behavior.

RYAN, M. J., University of Texas, Austin.
Neuroanatomy influences speciation rates among anurans.

ANURAN VOCALIZATIONS

CHAIR: J. C. MITCHELL

KRUPA, J. J., University of Oklahoma.
The seasonal influence on the breeding behavior of the Great Plains toad *(Bufo cognatus).*

PAGUE, C. A., J. C. Mitchell and R. L. Hoffman, Old Dominion University, University of Richmond, Radford University.

The distribution and mating calls of *Hyla chrysoscelis* and *H. versicolor* in Virginia.
PERRILL, S. A., Butler University.
Noncalling male strategy in the northern cricket frog *Acris crepitans.*
TOWNSEND, D. S. and W. H. Moger, Dalhousie University, Halifax, Nova Scotia.
Androgens and male parental care in the Puerto Rican frog *Eleutherodactylus coqui.*

REPTILIAN THERMAL ECOLOGY
CHAIR: ARTHUR C. ECHTERNACHT

YAMAKOSHI, M. and W. E. Magnusson, Instituto Nacional de Pesquisas da Amazonia, Manaus, Brazil.
Effects of termite mounds, metabolic heat of embryos and season on the temperature of nests of *Paleosuchus trigonatus.*
SMUCNY, D. A. and A. R. Gibson, Cleveland State University.
Heat use patterns in female common garter snakes, *Thamnophis sirtalis.*
LUIZAO, R.C.C. and B. Robertson, Instituto Nacional de Pesquisas da Amazonia Manaus, Amazonas Brasil.
Effects of temperature and insolation on the daily activity rhythm of *Cnemidophorus lemniscatus* in Amazonian savanna.
PAULISSEN, M. A., University of Oklahoma.
Thermoregulation of the six-lined racerunner, *Cnemidophorus sexlineatus* (Sauria:Teiidae): Age-specific comparisons.
WILSON, M. A. and A. C. Echternacht, University of Tennessee, Knoxville.
A portable, non-photo, thermal gradient for use with small arboreal lizards.

REPTILE TAXONOMY
CHAIR: DOUGLAS A. ROSSMAN

CRUMLY, C. R., Harvard University.
A cladistic analysis of the intergeneric relationships of land tortoises (Family Testudinidae).
DUNDEE, H. A. and D. A. White, Tulane University and Loyola University of the South.
Comments on the zoogeography, natural history, and systematics of some Yucatan peninsula amphibians and reptiles.
PETERSON, J. A. and J. W. Wright, Los Angeles Natural History Museum.
Scale surface microstructure of anguid lizards.
SWEET, S. S., University of California, Santa Barbara.
Patterns of scale-organ variation in western North American colubrid snakes.
ROSSMAN, D. A. and C. R. Stewart, Louisiana State University and California State Polytechnic University.
Taxonomic status of the California giant garter snake.

TURTLE REPRODUCTION AND ECOLOGY
CHAIRS: C. KENNETH DODD, DALE R. JACKSON, LEW M. EHRHART, RICHARD C. VOGT

WILLIAMS, E. C., Jr. and W. S. Parker, Wabash College and Mississippi University for Women.
A 27-year study of a box turtle *(Terrapene carolina)* population at Allee Memorial Woods, Indiana.
TURNER, F. B., K. H. Berry, B. L. Burge, J. B. Roberson, and P. Hayden, University of California, Los Angeles; U.S. Bureau of Land Management.
Egg production and nesting success in the desert tortoise *(Gopherus agassizii).*
BERRY, K. H., USDI, Bureau of Land Management, Desert District, Riverside, California.
The incidence of gunshot deaths in desert tortoise *(Gopherus agassizii)* populations in California.
WESTER, E. E., Auburn University.
Demography of predator-free island populations of the gopher tortoise, *Gopherus polyphemus.*
BROOKS, R. J., E. G. Nancekivell and D. A. Galbraith, University of Guelph.
Sex determination and hatchling sex ratio in northern population of *Chelydra serpentina.*
MAHMOUD, I. Y., M. McAsey*, E. James Aiman, C. Cady and R. V. Cyrus, University of Wisconsin-Oshkosh; *The Medical School of Wisconsin.
Levels of testosterone in testes during the testicular cycle of the snapping turtle, *Chelydra serpentina.*
HOTALING, E. C., Rutgers University, Newark.
Factors effecting sex ratio in nests of *Chelydra serpentina.*
WILHOFT, D. C. and E. C. Hotaling, Rutgers University, Newark.
Thermal parameters observed during onshore activity of *Chelydra serpentina.*

Announcement of ASIH 1986 Meeting

The 66th Annual Meeting of the American Society of Ichthyologists and Herpetologists will be hosted by the University of Victoria and the British Columbia Museum in Victoria, British Columbia, Canada, from 15-21 June 1986. Patrick Gregory (University of Victoria) and Alex Peden (British Columbia Provincial Museum) are co-chairmen. The University of Victoria campus will be the main venue for this meeting, with eating and dormitory facilities on-site. Three symposia will be held: 1) Snake Behavior and Ecology (organizer, N. Ford); 2) Physiology and Ecology of Ectotherm Hibernation (G. Ultsch); and 3) Systematics and Biology of Deep-sea Fishes (D. Stein). These symposia will feature the major researchers in their respective fields. An additional planned attraction is a workshop focussing on the application of immunological and molecular techniques to population genetics, systematics and other areas of biology (H. Dessauer). The American Elasobranch Society will meet concurrently with ASIH in Victoria and hold separate sessions. As well as the academic program, there will be a varied menu of social events, including a smoked salmon supper and logging display.

British Columbia is an ideal place to combine this professional conference with a family holiday. This will be especially true in 1986 when there will be a World's Fair (Expo '86) in Vancouver, across the Strait of Georgia from Victoria. A vast number of other holiday possibilities exist, ranging from relaxing at modern vacation resorts, through cruises up the coast to Alaska, to hiking in rugged mountain wilderness.

Proposed Registration Fees (in US funds)

i) Pre-registration

Regular	$40.00	Partner	$12.00
Student	$24.00	Banquet	$16.00
Student Stoye Award	$12.00		

ii) On-site

Regular	$60.00	Partner	$16.00
Student	$24.00	Banquet	$16.00
Student Stoye Award			

Transportation

Air Canada has been designated the official carrier for this meeting. They offer 20% discount on all regular economy fare tickets booked through Convention Central. We encourage you to take advantage of these low rates. Please identify yourself as a delegate to the meeting when reserving flights. Call 1-800-361-7585.

If you wish to receive an announcement of the meeting, including a call for papers and registration form, please write to:

GALBRAITH, D. A. and R. J. Brooks, University of Guelph.
Growth in a northern population of *Chelydra serpentina* (Cryptodira: Chelydridae).
MEYLAN, A. B., University of Florida.
Sponge predation by the hawksbill turtle, *Eretmochelys imbricata:* Structural and biochemical defenses of prey.
WITHERINGTON, B. E. and Ehrhart, L. M., University of Central Florida.
Hypothermic stunning of marine turtles in Florida east-coast lagoons in January 1985: A comparison with two previous cold-stunning episodes.
ROBINSON, D. and S. Cornelius, Univ. de Costa Rica, C.R. and R. R. 3, 216, Mountain View, MO.
Seasonal and periodic density of emerging olive Ridley sea turtles *Lepidochelys olivacea* on two Costa Rican beaches.
CHAVES, A. and D. C. Robinson, Universidad de Costa Rica, Costa Rica.
Initial viability of olive Ridley sea turtle eggs in Costa Rica.
FRAZER, N. T., Woods Hole Oceanographic Institution.
Survivorship from egg to adulthood in a declining population of loggerhead sea turtles, *Caretta caretta.*
PRITCHARD, P.C.H., Florida Audubon Society.
Hypothetical functional interpretations of neural bone variation in turtles.
VOGT, R. C., Universidad Nacional Autonoma de Mexico.
Terrestrial activity patterns of a neotropical turtle *Kinostern leucostomum.*
ERNST, C. H., George Mason University, Fairfax, Virginia.
Environmental temperatures and activities in the wood turtle, *Clemmys insculpta.*
GRAHAM, T. E., Worcester State College.
Aspects of the winter ecology of the endangered red-bellied turtle, *Pseudemys rubriventris,* in Southeastern Massachusetts.
SCOTT, D. E., F. W. Whicker and J. W. Gibbons, Savannah River Ecology Laboratory.
Seasonal variation in the field metabolic rates of the yellow-bellied slider *(Pseudemys scripta).*
LOVICH, J. E., University of Georgia, Institute of Ecology.
An analysis of aggressive basking behavior in wild Eastern painted turtles.
NOVAK, S. S. and S. J. Morreale, Savannah River Ecology Laboratory.
Survivorship and growth of hatchling *Pseudemys scripta* in saline environments.
SCHWARZKOPF, L. and R. J. Brooks, University of Guelph.
Annual variation in reproductive characteristics of painted turtles.
CONGDON, J. D. and J. W. Gibbons, Savannah River Ecology Laboratory.
Optimal egg size in turtles revisited.

SQUAMATE REPRODUCTION
CHAIR: SAMUEL S. SWEET

FERGUSON, G. W. and H. L. Snell, Texas Christian University.
Endogenous control of seasonal change of egg, hatchling and clutch size of the lizard *Sceloporus undulatus garmani.*
SOMMA, L. A., University of Nebraska at Omaha.
Egg brooding in the prairie skink, *Eumeces septentrionalis,* and its relationship to the hydric environment of the nest substrate.
RODDA, G. H., Smithsonian Institution, University of Tennessee.
The relative energetic costs of reproduction between the sexes in the green iguana, *Iguana iguana.*
STAHL, S. J. and J. C. Mitchell, University of Richmond.
Reproductive cycle of the copperhead, *Agkistrodon contortrix,* in Virginia.
SECOR, S. M., University of Oklahoma.
A comparative study of the reproductive behavior of three species of snakes, genus *Lampropeltis.*

SQUAMATE ECOLOGY
CHAIRS: NEIL B. FORD, RICHARD A. BYLES, STEVE GODLEY

SEIGEL, R. A., Savannah River Ecology Laboratory.
Ontogenetic variation in foraging ecology and niche overlap in garter snakes.
HOLLAND, D. L. and N. B. Ford, University of Texas at Tyler.
Aggregation tendency in adult checkered garter snakes, *Thamnophis marcianus.*
LORAINE, R. K., Savannah River Ecology Laboratory.
Seasonal changes in foraging success and diet composition of *Seminatrix pygaea.*
GREGORY, P. T. and K. W. Larsen, University of Victoria.
The ecology of garter snakes at the northern limit of their range.
GODLEY, J. S., Biological Research Associates, Inc.
Population ecology of kingsnakes *(Lampropeltis getulus)* at Rainey Slough, Florida.
STEINER, T. M. and G. H. Dalrymple, Florida International University.
Community ecology of a temperate zone fauna in the subtropics: The snakes of Long Pine Key, Everglades National Park, Florida.
SNELL, H. L., R. D. Jennings and H. M. Snell, Texas Christian University, University of New Mexico.
Intrapopulation variation in predator-avoidance performance of Galapagos lava lizards: Relationships among vegetation, sex, wariness, and sprint speed.
FLEISHMAN, L. J., Cornell University.
Motion detection in *Anolis* lizards and cryptic movement by a predatory snake.
LOSOS, J. B., University of California, Berkeley.
Island biogeography of day geckos *(Phelsuma)* in the Indian Ocean.
GUYER, C., University of Miami.
Effects of food supplementation on the demography of a tropical anoline lizard.
GASNIER, T.R.J., A. P. Lima and W. E. Magnusson, Instituto Nacional de Pesquisas da Amazonia, Manaus, Brazil.
Activity and diet of three rainforest lizards.
MORITZ, C., Australian National University and University of Michigan.
Parthenogenesis in the tropical gekko, *Nactus arnouxii.*
JENNINGS, M. R., The University of Arizona.
The Southern California horned toad trade: 1885-1930.
LAZCANO-BARRERO, M. A.[1], E. Gongora[1], and O. A. Flores-Villela[2], (1) INIREB, Chiapas (2) Facultad de Ciencias, UNAM, Mexico.
The Lacandon tropical rain forest herpetofauna: A preliminary report.
WERNER, D. I., Smithsonian Tropical Research Institute.
The influence of social factors on growth rate in juvenile *Iguana iguana.*
MARTIN, W. H.
Phenology of the timber rattlesnake, *Crotalus horridus.*
PORAN, N., University of California at Davis.
California ground squirrel anti-snake adaptations: Behavioral and immunological defenses.
de QUEIROZ, A., Pough, F. H., Andrews, R. M. and A. Collazo, Cornell University, Virginia Polytechnic and State University.
Lack of a temperture effect on prey handling costs in the skink *Chalcides ocellatus.*

SNAKE FORM AND FUNCTION
CHAIR: ALAN H. SAVITZKY

SAVITZKY, A. H., Old Dominion University.
The role of development in the evolution of ophidian pit organs: Hypothesized mechanisms.
McDOWELL, S. B., Rutgers University, Newark.
The homology of the venom gland and position of the proteroglyphs among colubroidea.
JAYNE, B. C., Michigan State University.
Muscular mechanisms of snake locomotion.
MACKESSY, S., Washington State University.
Venom storge and the accessory gland of *Crotalus v. oreganus.*
MARTIN, D. L., D. B. Means and O. G. Brock, Florida State University, Coastal Plains Institute and Florida Department of Natural Resources.
Patterns of foraging behavior in the Eastern diamondback rattlesnake, *Crotalus adamanteus.*
HARDY, D. L., College of Pharmacy, University of Arizona.
Deaths from *Crotalus* envenomation in Arizona.

SEXUAL SELECTION AND MALARIA
CHAIR: JULIAN C. LEE

MORRIS, M. R., Indiana University.
Mating behavior and sexual selection in the gray treefrog *(Hyla chrysoscelis).*
PAGUE, C. A., Old Dominion University.
Testis size reduction in mated *Bufo terrestris:* Implications for sexual selection.
LEE, J. C., University of Miami.
Is the large male mating advantage in anurans an epiphenomenon?
FORESTER, D. C. and D. V. Lykens, Towson State University.
Sexual selection in the spring peeper: Is call frequency an indicator of age?
SCHALL, J. J., University of Vermont.
Malaria and other blood parasites of lizards: Impact on hosts and those who study them.
RESSEL, S., University of Vermont.
Malarial infection and sexual selection in the Western fence lizard *Sceloporus occidentalis.*

WORKSHOP ON THE STATUS OF *Gopherus polyphemus*
CHAIRS: RICHARD FRANZ, REN LOHOEFENER

FRANZ, R., Florida State Museum.
***Gopherus polyphemus*, a species in decline: Introductory remarks.**
LANDERS, L., Tall Timbers Biological Station.
Ecology of the gopher tortoise in southwest Georgia.
OSTERMAN, T. R., University of South Florida.
Reproductive biology of the gopher tortoise.
DEIMER, J., Florida Game and Freshwater Fish Commission.
Gopher tortoise in Florida: Status and research.
DODD, C. K., U.S. Fish and Wildlife Service.
Implications of federal protection for the gopher tortoise.
JACKSON, D. R., Florida Natural Areas Inventory.
The future of the gopher tortoise. What happens next?
FIELDTRIP — To University of South Florida Ecological Research Area for workshop participants.

SSAR ZOO LIAISON COMMITTEE SYMPOSIUM: ECOLOGY AND REPRODUCTION OF WEST INDIAN HERPETOFAUNA
CHAIR: PETER J. TOLSON

TOLSON, P. J., T. A. Reichard, J. M. Terry, C. S Roberts and D. H. Clifford, Toledo Zoological Society; Medical College of Ohio.
Effects of courtship on follicular growth and development in the Cuban boa, *Epicrates angulifer* (Serpentes: Boidae).
TEUBNER, V. A., P. J. Tolson and C. P. Black, University of Toledo, Toledo Zoological Society.
Effects of proximate environmental factors on serum testosterone levels of the Haitian boa *(Epicrates striatus).*
ULRICH, N. and N. B. Ford, University of Texas at Tyler.
The feeding strike of three species of vine snake, *Uromacer.*
JENSSEN, T. A. and D. L. Marcellini, Veterans Administration Tech, National Zoological Park, Washington, D.C.
Seasonal effects upon density and microdistribution of sympatric anoline lizards.
SARMIENTO, R., Oklahoma City Zoo.
Behavioral observations and captive maintenance of the dwarf anole, *Anolis occultus* (Sauria: Iguanidae).
CRUTCHFIELD, T. E., Herpetofauna Inc., Ft. Myers, Florida.
Captive maintenance and propagation of the West Indian iguanid genus *Cyclura.*
MARCELLINI, D. L. and T. A. Jenssen, National Zoological Park, Washington, D.C.
Thermoregulation and activity patterns in the Haitian lizard *Leiocephalus schreibersi.*
WOOD, J. R. and F. E. Wood, Cayman Turtle Farm (1983) Ltd. B.W.I.
Breeding green sea turtles in captivity.

9th ANNUAL REGIONAL HERPETOLOGICAL SOCIETY CONFERENCE "METHODS TO ENHANCE THE REGIONAL SOCIETIES" SPONSORED BY THE SSAR REGIONAL HERPETOLOGICAL SOCIETY LIAISON COMMITTEE
CHAIR: TERRY HIBBITTS

SIMMONS, J. E., Kansas Herpetological Society.
Newsletter techniques used by the Kansas Herpetological Society.
ROSENBERG, M. J., Northern Ohio Association of Herpetologists.
How newsletters can promote regional societies.
VERMERSCH, T., Greater San Antonio Herpetological Society.
Procedures used in the presentation of public live-animal displays by regional societies.
COLLINS, J. T., Kansas Herpetological Society.
The use of auctions as a method to enhance regional societies.
FERGUSON, G. W., Texas Herpetological Society.
Problems of organizing an annual conference.
MEYLAN, P., All Florida Herpetological Conference.
The structure and future of the All Florida Herpetological Conference.
MURPHY, J., Chicago Herpetological Society.
Field trips and the Chicago Herpetological Society.
HIBBITTS, T., Texas Herpetological Society.
The Texas Herpetological Society and forty years of field trips.

POSTERS

KLEESE, W. C. and D. E. Goll, Muscle Biology Group, University of Arizona.
Localization of the CA^{2+}-dependent proteinase and its inhibitor in different tissues of *Crotalus atrox.*
MANIS, M. L., Miami University.
Allozyme variability among *Rana sylvatica* populations.
MINTON, S. A. and S. A. Weinstein, Indiana University and New York University.
Geographic and ontogenic variation in venom of the western diamondback rattlesnake *(Crotalus atrox).*
SCOTT, N. J., JR. and R. D. Jennings, Denver Wildlife Research Center, Museum of Southwestern Biology and University of New Mexico.
The tadpoles of five New Mexican leopard frogs.
STOVALL, R. H. and S. Myers, Valencia Community College and University of Central Florida.
Photographic survey of the reproductive cycle of the peninsula ribbon snake *(Thamnophis sauritus sackeni).*
MYERS, S. and R. H. Stovall, University of Central Florida and Valencia Community College.
Reproductive biology of the peninsula ribbon snake *(Thamnophis sauritus sackeni).*
SANAIOTTI, T.M., Instituto Nacional de Pesquisas da Amazonia.
Home range and body size in lizards: Conceptual, statistical and empirical models.
DePARI, J. A., M. H. Linck and T. E. Graham, Rutgers University, Worcester State College.
Clutch size of the Blanding's turtle, *Emydoidea blandingi*, in Massachusetts.
HARDING, J. H., Cranbrook Institute of Science.
Comments on age determination and growth in a Michigan population of the wood turtle *(Clemmys insculpta).*
MORREALE, S. J. and J. W. Gibbons, Savannah River Ecology Laboratory.
Adult sex ratios in natural populations of turtles.
RAYMOND, P. W. and C. A. Orvetz, National Marine Fisheries Service.
The TED (turtle excluder device): How it works to prevent sea turtle mortality in shrimp trawls.
WYNEKEN, J., University of Illinois.
The implication of allometeric changes in the limb and body proportions of two species of sea turtles, *Caretta caretta* and *Chelonia mydas.*
LEWIS, A. R., University of Puerto Rico.
Body size and growth in two populations of the Puerto Rican ground lizard.
MACDONALD, L. A., University of South Florida.
The diet of the gopher tortoise *(Gopherus polyphemus)* in a sandhill in Central Florida.
WEIG, B. and R. C. Wood, Stockton State College.
Evolution of African Trionychid (Soft-shelled) turtles.
ROCEK, Z., Charles University, Prague, Czechoslovakia.
Main features of the endocranial development in pipids.

LETTER TO THE EDITOR

AN OPEN LETTER TO ALL HERPETOLOGISTS

We wish to add our expressions of concern to those in earlier letters to *Herpetological Review* (King and Miller 1985; Heatwole 1985; Gans 1985; Tyler 1985) about two recent herpetological publications and to advise our intended response to the deplorable situation that has developed recently in Australia. For reasons given below and in anticipation of a successful case being made to the International Commission on Zoological Nomenclature, WE INTEND TO IGNORE ALL NOMENCLATURAL AND TAXONOMIC CHANGES PROPOSED BY WELLS AND WELLINGTON (1984, 1985). The publications which have sparked such controversy appear in two recent issues of the privately published "Australian Journal of Herpetology." They are authored by Richard Wells and Ross Wellington, who also edit the journal. The papers comprise checklists and/or synopses and/or revisions of the whole Australian herpetofauna. They occupy entire sequential issues, Volume 1 Parts 3 and 4 (combined) and Supplement Series No. 1, and propose extensive nomenclatural and taxonomic changes, including the erection and resurrection of hundreds of genera and species. Adequate diagnoses are lacking throughout and rea-

sons for proposed changes are not given except in a few instances.

Some details about the history of the journal have been given in the letters cited above. Previous issues (Volume 1 Parts 1 and 2) contain refereed papers by several authors on a variety of topics, and a number of professional herpetologists acted as an advisory board. None of these knew about the taxonomic reviews proposed for the third and fourth issues and they resigned immediately following the first of these (King and Miller 1985; Heatwole 1985).

We do not fully understand the motivation of Wells and Wellington for publishing these massive and poorly justified nomenclatural and taxonomic changes (which they acknowledge, in their preface to the 1984 paper, may be seen as 'anarchistic taxonomic vandalism'). However, the effect of these publications, if taken seriously, would be to destabilise permanently the nomenclature of the Australian herpetofauna. In our view, to accept the proposed changes is to accept the proposition that taxonomic revision may be undertaken without any attempt at justification of changes, without the usual refereeing process and, presumably, by anybody who has opinions and the money to have them published.

The Australian Society of Herpetologists voted overwhelmingly at its Annual General Meeting in September 1984 to apply to the International Commission on Zoological Nomenclature for formal suppression of the first of these two publications in its entirety (Shine 1985). It can be assumed that the same decision would flow from a similar meeting concerning the second issue, if one were held. A letter foreshadowing the application for suppression of both issues has been forwarded to the Secretary.

Scientists in Australia and elsewhere may be wondering whether or not to take note of the proposed changes. Accordingly, we now advise that we intend to ignore the taxonomic and nomenclatural changes proposed in these two publications. Our reasons are those already alluded to and because we subscribe to the view, in agreement with the Code, that it is desirable to provide "the maximum universality and continuity in the scientific names of animals, compatible with the freedom of scientists to classify animals according to taxonomic judgements." We encourage others also to ignore these publications. Further, we urge caution in accepting nomenclatural changes which are foreshadowed for further publications of this and other journals from the same stable, to include similar treatment for the Australian fishes, the Pacific herpetofauna and Australian Buprestidae (Coleoptera).

Finally, we wish to assert our belief that taxonomic researchers should feel obliged to meet at least minimum standards with respect to justification of decisions and recommendations made. Normally this restraint is self-imposed and is encouraged by the knowledge that acceptance for publication will depend upon the judgement of referees (whose identity is usually unknown to the author). Whereas this undoubtedly has shortcomings, it seems to have provided at least some check on taxonomic anarchy. It may be, however, that present happenings in Australia are uncovering a need for stricter guidelines.

NEWSNOTES

SUMMER COURSE ON PLETHODONTID SALAMANDERS

The Highlands Biological Station, located in the Southern Blue Ridge Mountains in Highlands, North Carolina, will offer a course on "The Biology of Plethodontid Salamanders," 7 July-8 August 1986. The instructor will be Dr. Stephen G. Tilley of Smith College.

The southern Appalachian region is renowned for the diversity of its salamander fauna. This course is designed to both acquaint students with plethodontid salamanders and to show how studies of these animals have enhanced our understanding of a series of major evolutionary and ecological topics. Each of these topics will occupy one week of the course, and be treated by lectures, field and laboratory exercises, and discussions of original research papers. Numerous field trips to significant salamander localities are a highlight of the course.

Six semester hours of credit are available through either Western Carolina University or the University of North Carolina at Chapel Hill.

For further information and application forms write Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, U.S.A. ●

REQUEST FOR INFORMATION

Over the past few years the Memphis Zoo and Aquarium and the Lichterman Nature Center, Memphis, Tennessee, have been working with a technique for repairing turtle shell fractures. The use of fiberglass mat and polyester resin enabled injured specimens to be repaired and released after recuperation. This technique has been used in the past for shell defects in tortoises. We have repaired and rehabilitated approximately a dozen specimens of red-eared turtle *(Pseudemys scripta elegans)*, Eastern box turtle *(Terrapene c. carolina)*, and three-toed box turtle *(T. c. triunguis)*. We invite anyone with experience or interest on this topic to correspond.

HERPETOPATHOLOGIA

The journal of the International Group on Herpetopathology publishes research articles, reviews and short notes on diseases of reptiles and amphibians, covering physiopathology, immunology, neoplasia, microbiological and parasitic diseases, teratology and environmental injury.

Papers presented at the Colloquia organised by the International Group will also be published in Herpetopathologia.

Libraries or individuals interested in subscribing to the journal should contact:

INFORMATION REQUEST

Inventories are requested for inclusion in the "Inventory of Live Reptiles and Amphibians in Captivity."

In the 1986 edition, the bibliography on husbandry and captive breeding will be expanded. Everyone is asked to contribute by sending in titles which may be beneficial to others. The 1986 revision will also expand the longevity records. Include dates for any specimen which may be a new longevity or noteworthy record.

Please submit the following information current 1 January 1986:

(1) A complete inventory of all reptiles and amphibians held. Sexes should be listed "male (1.0) female (0.1) unknown (0.0.1)."
(2) A list of species which bred and produced young during 1985, including numbers of young for each species.
(3) Miscellaneous breeding information not previously submitted.
(4) Possible longevity records. List total number of years, months, and days the specimen has been in captivity, and whether the animal is still living.
(5) A listing of any publications relating to reproduction in reptiles and amphibians. Emphasis should be placed on "How to do it" publications, but general articles, and references relating to temperature, light cycle, hibernation, etc. are also of interest.
(6) When submitting inventories, follow the taxonomic order listed in the 1985 edition. Type or print legibly and include your complete address and phone numbers as you would like them listed.

All information should be sent to:

Frank L. Slavens
P.O. Box 30744
Seattle, Washington 98103, U.S.A. ●

IN MEMORIAM

Dr. Braulio Orejas-Miranda, the well-known herpetologist, passed away on 8 May 1985, at the age of 52. At the time he was Program Specialist at the UNESCO's Regional Office for Science and Technology for Latin America and the Caribbean, at Montevideo, Uruguay, the culmination of a long scientific career.

Orejas-Miranda was born in Montevideo, Uruguay, on 19 February 1933. In the same city, he obtained a Primary School teacher degree, and then a Licenciado degree in Biological Sciences from the University of the Republic. His postgraduate training was at the University of São Paulo, Brazil, the Central University of Venezuela, and at the University of Michigan, USA, where he focused on natural resources management and conservation.

From the very beginning Orejas-Miranda divided his time between scientific research in herpetology and science policy and conservation problems. In this second area, he worked as a secondary education teacher, National Overseer for Sciences at the Primary School Education Council, and taught at the teacher's formations institutes of Montevideo

and San José. He also held teaching positions in other countries: Professor at the Central University of Venezuela, and Professor at the School of Medicine, Universidad del Valle, Colombia. His interests in conservation led him to involvement with many zoos, particularly the Caracas Zoo, of which he was Director.

Prior to his position with UNESCO, he was a Specialist at the Basic Sciences Unit, Organization of American States, Washington, USA. In that position he reviewed research projects in the Americas, allowing him to keep abreast of the scientific activities on the continent. He participated in the conservation movement from the very beginning, with the Club of Rome's "The Limits to Growth" and the 1972 United Nations Conference at Stockholm. While with the OAS he contributed to the Institute of Ecology's books "Man in the Living Environment" and "Fragile Ecosystems."

His work in herpetology began with his research positions with the National Museum of Natural History of Montevideo, and the "Clemente Estable" Institute of Biological Research. Soon after, he began a close friendship with the late James A. Peters, and Orejas-Miranda was appointed as research associate at the Smithsonian Institution, Washington, D.C. With Peters he wrote the now classic Snakes volume of the "Catalogue of the Neotropical Squamata" (1970), a primary reference to the herpetology of the region. His research involved the Leptotyphlopidae, and produced numerous contributions, including descriptions of several new taxa. This interest led him to most Latin American herpetological collections, and to the most important ones in the U.S. and Europe. He was one of the first herpetologists to start a serious analysis of this small snake, and his contributions have been a landmark. In his recent position at UNESCO he worked with the Man and the Biosphere Program (MAB), and maintained close contact with almost all Latin American herpetologists.

During this long career Orejas-Miranda received many awards: The Guggenheim Award; the Condecoración Duarte, from the government of the República Dominicana; the Portuguese Parque Pineda Ceres medal; and a formal recognition from the OAS for his outstanding work.

Orejas-Miranda had a variety of talents and interests. He was a fine photographer and a good handyman, maintaining a home workshop. He was a likable and warm person,

always active. He retained his youth and I'll never forget him driving his Japanese motorcycle from one place to the other in the city. My loss is great: Since his return to Uruguay, in May 1982, I benefitted greatly from Orejas-Miranda's friendship and scientific guidance, as have many other Uruguayan biologists. The Latin American scientific community has lost one of its most brilliant biologists.

SOCIETIES

KANSAS HERPETOLOGICAL SOCIETY

The Kansas Herpetological Society is a conservation-oriented group of people interested in amphibians and reptiles. Founded in 1974, membership has now grown to nearly 200 members worldwide.

The annual meeting is held in a different part of Kansas each fall, and one or more field trips are conducted in the spring and early summer. The Kansas Herpetological Society Newsletter is published four times a year, and runs 18-26 pages per issue. The Society also publishes special publications from time to time which are distributed free to members.

Membership includes a subscription to the Kansas Herpetological Society Newsletter, and is open to anyone with an interest in amphibians and reptiles. Dues for calendar year 1986 are as follows:

Regular member (US)	$ 5.00
Non-US member	$ 8.00
Contributing member	$15.00

Make checks or money orders payable to KHS and provide precise mailing address with your payment. Send subscription requests to:

Larry Miller, Secretary-Treasurer
Kansas Herpetological Society
524 North Osage Street
Caldwell, Kansas 67022, U.S.A. ●

MINNESOTA HERPETOLOGICAL SOCIETY

The Minnesota Herpetological Society has recently published the "Distribution Maps of Minnesota's Amphibians and Reptiles," available from MHS for $4.50 postpaid.

MHS has initiated an Occasional Paper Series on a wide range of topics. Papers are being solicited and will be reviewed by two referees. Manuscripts should be sent to the address below.

MHS is completing its second survey of the amphibians and reptiles of Minnesota. The 1985 survey took place in Southeast Minnesota and was funded with a joint grant of $1700 from the Minnesota Nongame Program and the Minnesota TNC for $1700.

For further information, contact:

Bell Museum of Natural History
10 Church Street S.E.
Minneapolis, Minnesota 55455, U.S.A. ●

(Editor's Note: Regional Herpetological Societies are invited to submit short (250 words) descriptions of their activities, publications, and dues structures, for publication in this column.) ●

FEATURES

DISTRIBUTION OF THE LIZARD *Anolis cooki*, WITH COMMENTS ON ITS POSSIBLE FUTURE EXTINCTION

Instances of natural extinction are rarely observed, even though it is a major process predicted by evolutionary theory. However, the Puerto Rican lizard *Anolis cooki*, may be a species about to disappear due to naturally occurring phenomena (Williams 1972). Recent studies by Ortiz and Jenssen (1982) and Jenssen, Marcellini, Pague and Jenssen (1984) have shown that *A. cooki* is in direct

interference competition with *Anolis cristatellus*, where *A. cristatellus* is the dominant species. These studies revealed that when the two species are sympatric, *A. cristatellus* displaces *A. cooki* from complex microhabitat (i.e., trees and large bushes) into dead snags and small shrubs. In addition, field and lab-held encounters between the species have shown *A. cooki* to be aggressively dominated by *A. cristatellus*. What makes *A. cooki* a strong candidate for extinction is its limited and peculiar distribution which is largely sympatric with its more ubiquitous competitor, *A. cristatellus*.

In this report, we verify and expand the known range of *A. cooki* and give a detailed description of distribution for an important segment of the species' range. Our objective is to determine whether or not the distribution of *A. cooki* is shrinking. This report provides the initial observations of longitudinal study.

METHODS

While *A. cristatellus* is found throughout Puerto Rico, *A. cooki* is restricted to the southwestern part of the island (Fig. 1). We conducted censuses in the latter during August 1980, January 1982 and November 1983. A four-wheel drive vehicle was used to census an area along the coast from the Cabo Rojo Peninsula on the west to beyond the Guanica Forest Reserve in the east, and from the coast as a southern boundary to several kilometers inland as a northern limit. We used all available roads and tracks as east-west and north-south transects, stopping 5-15 times per kilometer to search surrounding habitat for *A. cooki* and *A. cristatellus*. Lizards were noosed, identified and released. In addition, the entire Cabo Rojo Peninsula was censused on foot to produce a microdistribution of the two species. Extensive ecological data on *A. cooki* and *A. cristatellus* at the Cabo Rojo locality appear elsewhere (Jenssen et al. 1984).

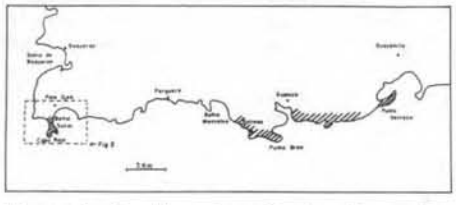

Figure 1. Southwestern Puerto Rico with diagonal lines showing approximate distribution of *Anolis cooki*.

RESULTS AND DISCUSSION

Our results confirmed the previously reported localities for *A. cooki* (Rivero 1978) and found additional sites on both sides of Salinas (Fig. 1). The large gap (~ 25 km) between the Cabo Rojo population and a population 3 km southwest of Salinas is verified. There is a small disjunction between the Punta Brea and Guanica populations, and another small gap about 9 km southeast of Guanica to the base of Punta Verraco. All *A. cooki* localities are less than 1 km from the coast. In contrast, *A. cristatellus* was found throughout the censused region.

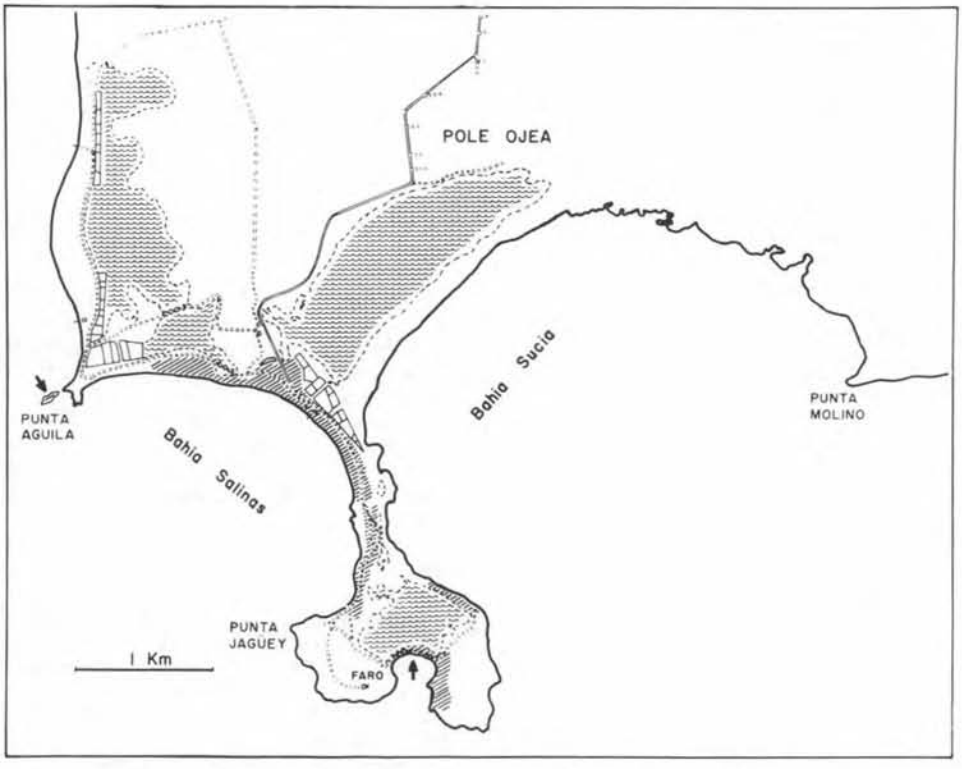

Figure 2. The peninsula at Cabo Rojo. Wavy lines show inland or brackish water, parallel dashed lines indicate unimproved roads, irregular polygons mark evaporation impoundments, and diagonal lines delineate the *Anolis cooki* distribution, with arrows indicating where the species was allopatric to *Anolis cristatellus* prior to 1983.

Except for the Cabo Rojo Peninsula, all visited localities in which *A. cooki* was allopatric (on a micro-scale) to *A. cristatellus* were xeric limestone ridges vegetated with cacti and thorny scrub. In adjacent mesic areas with trees and extensive shade, *A. cooki* was sympatric with *A. cristatellus*. Though not quantified, it was obvious that as one censused away from the xeric hillsides, the likelihood of encountering *A. cooki* dropped to zero after a few hundred meters, while *A. cristatellus* continued to be common.

The above qualitative observations plus ecological data from a study at Cabo Rojo (Jenssen et al. 1984) suggest that the xeric ridge habitats are refugia for *A. cooki* from the competitive effects of *A. cristatellus*. At Cabo Rojo, *A. cooki* and *A. cristatellus* both prefer to perch on trees and large bushes, but where the two are in microsympatry, *A. cooki* is restricted to more open microhabitat (Jenssen, et al. 1984). Similar to the open Cabo Rojo habitat, it is likely that the xeric limestone ridges provide a non-preferred habitat for *A. cooki* which is exclusive of *A. cristatellus*.

On the Cabo Rojo Peninsula, there is no xeric limestone habitat that typifies *A. cooki* habitat in other parts of its range. There are also no extensive areas where *A. cooki* is allopatric to *A. cristatellus*. *Anolis cristatellus* is more extensively distributed on the peninsula than *A. cooki*, being common except on salt flats and the plateaus above the escarpments at the southern tip of the peninsula (Fig. 2). There were only two areas where we found *A. cooki* without *A. cristatellus*. One was a small cay off Punta Aquila and the other a low-lying crescent of land at the southern end of the peninsula. In 1980 and 1982 the latter was the only extensive allopatric *A. cooki* area, and *A. cristatellus* had invaded by the time of the 1983 census.

The current distribution of *A. cooki* indicates that the species once had a more extensive range. Thomas and Schwartz (1966) suggested that in the past, the southwestern region of Puerto Rico could have been isolated from the main island mass by a higher than present sea level. The low llanos to the north of the *A. cooki* distribution completely surrounds all present-day *A. cooki* populations, and in the scenario may have been a channel. *Anolis cooki* could have evolved and populated this smaller island land mass in isolation from *A. cristatellus*. Then when a falling sea level re-joined the two islands, *A. cooki* became exposed to the euryecious colonizer, *A. cristatellus*. Subsequent competition between the two species resulted in the spotty, limestone ridge-centered populations of *A. cooki*. The Cabo Rojo population of *A. cooki* may be the most unstable because of the absence of limestone ridges for refugia and any nearby population as sources for recolonization.

With its limited and disjunct distribution and its competition with the more aggressive common *A. cristatellus*, *A. cooki* is a candidate for natural extinction. Our data provide an initial vantage point from which to monitor the species' possible extinction.

ACKNOWLEDGMENTS

We are grateful to David Barker, Bela Demeter, Lars Jenssen and Peter Ortiz for their assistance in the field. Our special thanks to Richard Thomas of the University of Puerto Rico for sharing his *A. cooki* locality records with us. The four-wheel drive vehicle was generously furnished by the Department of Natural Resources of Puerto Rico.

FIELD NOTES ON *Otophryne robusta steyermarki*

This subspecies was described by Rivero (1967) on the basis of a male and a female collected by J. Steyermark in 1955 and 1953 respectively on the Chimantá-tepui massif in southern Venezuela. During February 1984 the author located a population of *O. r. steyermarki* in the northeastern sector of the central part of Chimantá-tepui (05°19'N, 62°07'W, 2140 m), and collected an additional four specimens. The data for these specimens (MBUCV:6178, 6179, 6180, 6181) and an example of the lowland subspecies *O. r. robusta* (MBUCV 6182) that was collected to the east of the Chimantá-tepui massif in Pratawaga (04°57'N, 61°26'W, 960 m) are presented in Table 1. All five specimens are males.

The live colors of the highland subspecies were very contrasting when compared to the lowland form. All *O. r. steyermarki* had a light yellow line from the heel to the tip of the outer toe, and distinct bright yellow lines along the lateral folds which continued onto the thighs and shanks. These markings were absent in the lowland subspecies. The dorsum of MBUCV 6178 was dark brown with rufous blotches bordered in black, and the ventral surface reddish brown with yellow infuscations. The dorsum of MBUCV 6179 was gray with rufous blotches bordered in black. MBUCV 6180 had a rufous dorsum with faint dark blotches, and a pale ventral surface with dark marmorations. The dorsum of MBUCV 6181 consisted of chocolate brown marmorations on an ochre surface, and a brown belly with yellow spots. The dorsum of MBUCV 6182 was dark rust color, the throat pale grayish brown, the ventral surfaces of the limbs and belly pinkish gray, and the chest gray with faint brown speckling. The coloration of the latter was cryptic, and blended very well with the dry leaf substrate on the dry stream bed of the montane forest in which it was found.

Males of *O. r. steyermarki* were located along a rocky stream that appeared to be very oligotrophic. The only other organisms found in the stream were occasional caddis fly and may fly larvae. More than a kilometer of stream was examined. About half the length examined was bordered by *Bonnetia roraimae* woodland, and the rest by peat bogs. No birds usually associated with aquatic environments, such as kingfishers, herons or rails, were seen along the stream's course. Calling males were distributed along the bank of the stream in a clumped fashion. In any one clump the individual males were separated by several meters. There were estimated to be between 2 to 6 calling males per clump. The occurrence of clumps did not seem to be correlated with any obvious features such as vegetation or the presence of waterfalls. The overall density of calling males was in the order of 50 to 100 per kilometer of stream. Males called only during daylight hours (Figure 1).

A single nest of *O. r. steyermarki* was encountered. The entrance to the nest was almost level with the water level of the stream. The nest cavity was some 10 cm in diameter and contained a total of 24 large white noncapsulate eggs. These eggs were subsequently lost during a flash flood at another camp, and were therefore not measured. A photograph of one egg suggests that the total diameter (including albumen) was about 15 mm. While the nest was being opened the male retreated into a recess in the far wall of the nest cavity. Both nest and recess are presumed to have been constructed by the male rather than being natural cavities.

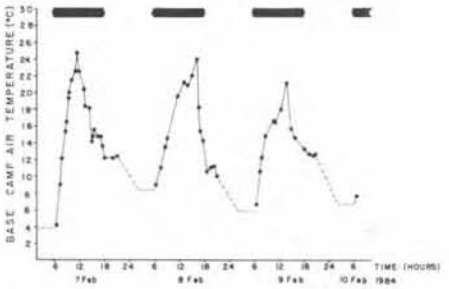

Figure 1. Calling periods for male *Otophryne robusta steyermarki* (horizontal bars) and air temperatures on Chimantá-tepui in February 1984.

Calling males apparently detected an observer when several meters away from their perch or tunnel, and ceased calling. This reaction was rather surprising considering the apparent absence of any diurnal predators. One possible predator was a diurnal snake, *Thamnodynastes chimanta*. It is, however, a small snake and probably could not swallow an adult *Otophryne*. Another possible predator was *Nasua nasua* that was observed at this locality. At another site some feces that were similar to those of *Nasua* were found to contain hylid frog bones and teeid lizard eggs.

Although a total of six localities were visited in the Chimantá-tepui massif by the author, *O. r. steyermarki* was only heard (but not collected) at Akopán-tepui (05°11'N, 62°00'W, 1920 m). Five days of field work on nearby Aprada-Tepui and nine days field work on Auyantepui did not reveal its presence in similar habitats. It is thus suggested that *O. r. steyermarki* is endemic with a restricted habitat on the Chimantá-tepui massif only.

ACKNOWLEDGMENTS

This report is an incidental result of an inventory of terrestrial ecosystems being carried out by C.V.G. Electrificación del Caroní C.A., The Instituto Venezolano de Investigaciones Científicas, the Universidad Central de Venezuela, and the New York Botanical Garden. The expedition to the Chimantá massif was partially financed by CONICIT grant # SI-1343 to Otto Huber. The author is indebted to AEREOTECNICA and the staff of the Campamento Canaima of C.V.G. Electrificación del Caroni C.A. for the excellent logistic support that was provided. The Chimantá massif is within the boundaries of the "Canaima" National Park, which is administered by the National Parks Institute of Venezuela.

THE DISTRIBUTION OF *Crocodylus acutus* IN CUBA

During the past 30 years I have been documenting the past and present distribution of *Crocodylus acutus* in Cuba. During this time many of the Cuban populations of *C. acutus* have become extinct due to predation and displacement by man. The growth of the human population and the expansion of agriculture during this century are directly responsible for the eradication of crocodiles in many localities. A lack of appreciation for the conservation of our fauna has also contributed to this decrease.

Currently *A. acutus* is most abundant (if the word can be used) in the brackish lagoons of the southwestern corner of Isla de Pinos and in Lanier's Lagoon. On the main island of Cuba the only substantive populations of the species are in the Cienaga de Zapata. In 1959, a great number of large specimens of *C. acutus* were collected from various localities and transported to "La Boca" in Guama, Cienaga de Zapata. Both *C. acutus* and *C. rhombifer* are penned together at Guama.

In Cuba, until about 1960, the distribution of *C. acutus* overlapped that of *C. rhombifer* in some areas — the upper portions of the Rio Hatiguanico, the adjacent river mouth, and to the south at Punta Gorda. Nevertheless, over most of their distribution the two species were allopatric.

The data here presented summarize the past and present distribution of *C. acutus* in Cuba. The following is a list of localities where *C. acutus* has been reported during this century. An asterisk (*) after the locality indicates that the presence of *C. acutus* was confirmed until December 1980. The number after the locality, indicates the map reference (Fig. 1). The pre-1960 names and boundaries of the provinces are used for the list of localities, but the map has the boundaries of the new provinces.

Pinar del Rio Province

— Northwestern coast of Guanahacabibes peninsula, from Cabo San Antonio to Guadiana*, in the coastal marshes and the several lagoons, mostly of brackish water.

— Playa Blancarena*, between Cabañas and Bahía Honda (1).

— Rio Bandera that drains into Bahía Ortigosa*; there are caymans from mouth to at least 6 km up stream (2).

— Las Compuertas ditch*, near La Jaula, Guanahacabibes (3).

— Laguna Lugones* (4).

— Laguna Yagua* (5).

— Los Palacios (6).

— Laguna el Tablazo*, some 10 km from the mouth of the Rio San Diego, to the south of Herradura; fresh water (7).

— Rio Dominica*, 7 km up stream (8).

— Laguna Maldonado*, in Catalina de Guane; fresh water (9).

NOW AVAILABLE
1985 INVENTORY - BIBLIOGRAPHY - BREEDING REPORT

THE 1985 "INVENTORY OF LIVE REPTILES AND AMPHIBIANS IN CAPTIVITY, CURRENT JANUARY 1, 1985", compiled by Frank L. Slavens, contains a combined inventory of 260 collections from 16 countries. Information is current as of January 1st, 1985 with 446 genera, 1,211 species, and 1,691 forms represented.

This multi-use reference allows one to search any of the 1,691 forms of reptiles or amphibians reported by the 260 responding collections and find the number of male, female, or unknown sex, held by each collection. If a species was bred during 1984 the reported dates of copulation, egg laying, hatching, etc. were included. Longevity records were included for the first time in this edition and the breeding bibliography was expanded to 977 titles pertaining to husbandry, diet, temperature, light cycle, etc.

PUBLISHED BY THE AUTHOR, P.O. Box 30744, Seattle, Washington 98103. 1985. 342 pages. $32.50 hardbound, $25.00 paperbound, plus $2.50 postage, $3.50 postage overseas.

INFORMATION FOR THE 1986 EDITION IS NOW DUE. CONTACT FRANK SLAVENS AT THE ABOVE ADDRESS FOR FURTHER INFORMATION.

ANNOUNCING
A LIMITED TIME 25% DISCOUNT SALE FOR SELECTED SSAR PUBLICATIONS

The following publications are offered at a 25% discount (from our 1986 price sheet) for orders received prior to June 30, 1986.

Journal of Herpetology, Vols. 13-18 only: Prices reduced from $5.00 to $3.50 per individual number of each volume.

Herpetological Review, Vols. 1-15: All volumes and numbers that are in stock (see below for out-of-print numbers). Prices reduced from $2.00 to $1.50 per individual number of each volume.

Herp. Review Nos. Out-of-Print:

Vol. 1 No. 7 (1969)	Vol. 5 No. 2 (1974)
Vol. 3 No. 2 (1971)	Vol. 6 No. 1 (1975)
Vol. 4 No. 1 (1972)	Vol. 10 No. 2 (1979)

Cumulative Index to volumes 1-10 of Journal of Herpetology. *$3.50.*

Cumulative Index to Herpetological Review, 1967-1976. *$1.50.*

Catalogue of American Amphibians and Reptiles: Imprinted binder, taxonomic tabs, and accounts 1-390. *$277.50.*

Silver Anniversary Membership Directory (Herp. Circular 13), including addresses of all SSAR members, addresses and publications of the herpetological societies of the world, and a brief history of the Society. 1983, 56 p., 4 photographs. *$1.50.*

RECENT HERPETOLOGICAL LITERATURE: Number 1 (1983), 66 p. *$3.00.*
Number 2 (1984), 38 p. *$3.00.*

Color Print
SILVER ANNIVERSARY COMMEMORATIVE PRINT. A full-color print (11.5 x 15.25 inches) of a Gila Monster *(Heloderma suspectum)* on natural background, from a watercolor by David M. Dennis. Issued as part of Society's 25th Anniversary in 1982. Each *$5.00.*

Send orders to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio, 45056, USA. Please make checks payable to "SSAR." All USA orders are postpaid; shipments outside the USA will be charged only the *additional* shipping costs in excess of domestic rates. Overseas customers must pay in USA funds or by International Money Order, or may charge to MasterCard or Visa (give account number and expiration date). A complete list of Society publications and membership information can be obtained from Dr. Taylor.

— Laguna del Fraile*, near San Julian (10).

— Playa Punta Colorada*, Guane. I examined a female, 4 m in length (11).

— La Jítima*, Hoyo de Marpostón, near San Cristobal (12).

— Laguna de Piedra*, between Candelaria and San Cristóbal, in the south coast; fresh water (13).

Habana Province

— Southern coast*, near El Cajío, to the west of Batabanó.

Matanzas Province

— Coastal zone (septentrional), north of Itabo.

Las Villas Province

— Coastal zone in the southwest, between Rio Hatiguanico and Punta Gorda*, in western portion of the Cienaga de Zapata. Also in nearby small lagoons and canals; brackish water. Very few individuals in the mouth of Rio Hatiguanico, due to human presence. Very abundant a few years ago.

— Coastal zone*, south of Playa Caimito (14).

— Ciénaga de Yaguajay, to the east of Caguanes, in the north coast (15).

— Estero de Macurije*, to the east of Casilda: more than 100 individuals were captured in 1962 for the enclosures in Zapata (18).

— Estero La Alegría*, near Casilda (19).

— Rio Agabama*, near Trinidad, southern coast (22).

— Rio Manatí*, (21).

Camagüey Province

— La Palmita, in the south coast (16).

— La Güira*, near Verraco, in Caonao; freshwater lagoon (17).

— Rio San Pedro* (20).

— Coastal zone, in the south, between Santa Cruz del Sur and Playa Florida (23).

Oriente Province

— Cobarrubia point, to the west of Puerto Padre (24).

— Cienaga de Birama or Buey*, from Rio Cauto to Manzanillo (25).

— Laguna Baconao*, near Caney; brackish water (26).

— Laguna Sevilla, to the west of Santiago (27).

— Yateritas zone, between Caimanera and Baracoa (28).

Isla de Pinos

— Rio Júcaro, 6 km to Santa Fe (29).

— Cienaga Lanier*, from west to east (30).

— Bahia Siguanea* (31).

Sabana-Camagüey Archipelago

— Cayo Santa María, to the northeast of Caibarién* (32).

Canarreos Archipelago

— Cayo Largo*; an interior lagoon, and the coasts (33).

— Cayo Cantiles*; in brackish water lagoon to the southeast; some individuals larger than 3 m (34).

— Cayo Estopa* (35).

— Cayo de la Piedra* (36).

— Cayos Maja* (37).

— Cayo Diego Perez* (38).

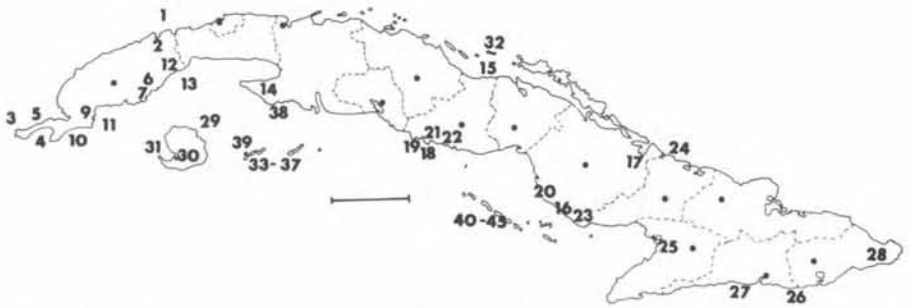

Figure 1. Map of Cuba showing the location of some of the localities from which *Crocodylus acutus* has been reported. See text for list of localities. The provincial boundaries on the map are for the new provinces established after 1960. The black dots represent the provincial capitals. Scale = 100 km.

— Cayo Avalos* (39).

Doce Leguas Archipelago

— Cayo Breton*, an interior lagoon (40).

— Cayo Cinco Balas* (41).

— Cayo Caballones* (42).

REDISCOVERY OF *Tantilla bairdi* STUART AND A DEFINITE GUATEMALAN LOCALITY FOR *Tantilla taeniata* (BOCOURT)

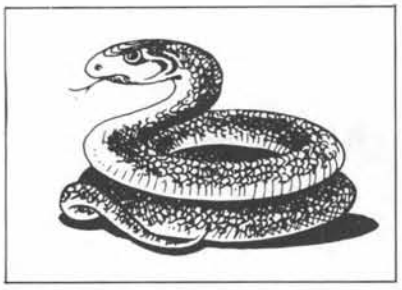
The Central American species of *Tantilla* were recently reviewed by Wilson (1982). He listed but a single specimen of *T. bairdi*, the female holotype, described by Stuart (1941). No definite record for Guatemala exists for *T. taeniata* (Bocourt), even though the holotype is from that country (Wilson 1982).

A specimen of each species was recently collected in Guatemala and was made available to me by Jonathan A. Campbell. *Tantilla bairdi* (KU 191102) was collected 5 km S La Union Barrios at Agua Zarca at an elevation of 1524 m in the department of Baja Verapaz on 22 August 1980 by P. Lucas Pineda for J. A. Campbell. It is an adult male and, thus, represents the first known male for the species from the second known locality. It possesses the following characteristics: 163 ventrils; 36 subcaudals; ventrals + subcaudals 199; dorsal scale rows 15-15-15; anal plate divided; supralabials 7-7 (3rd and 4th entering orbit); infralabials 6-6, first pair not in medial contact, 4 in contact with anterior chin shields; preocular single and in contact with postnasal; postoculars 2-2; temporals 1+1; total length 455 mm; tail length 65 mm; tail length/total length 0.143. These data are in close agreement with those of the female holotype (Wilson 1982). No data are available on color in life. The color in preservative is as follows: dorsum dark brown; venter pale orange (bright red-orange in life?); head same color as dorsum; nuchal collar, pre- and postocular spots cream.

The *Tantilla taeniata* (KU 187350) came from 10.4 km N Santo Tomas at an elevation of 585 m in the department of Izable. It was collected on 19 June 1980 by Jonathan A. Campbell, Linda S. Ford, and K. Kennedy. It is an adult female and represents the first definite locality data from Guatemala. It possesses the following characteristics: 165 ventrals; 69 subcaudals; ventrals + subcaudals 234; dorsal scale rows 15-15-15; anal plate divided; supralabials 7-7 (3rd and 4th entering orbit); infralabials 6-6, first pair not in medial contact, 4 in contact with anterior chin shields; preocular single and in contact with postnasal; postoculars 2-2; temporals 1+1; total length 389 mm; tail length 90 mm; tail length/total length 0.231. These data are in agreement with those given by Wilson (1982) for this species, except that the subcaudal count is 5 scales above the range (58-64) given in that paper.

Jonathan A. Campbell kindly allowed me to examine a color slide of KU 187350 in life. The coloration is typical of *T. taeniata*. The middorsal stripe is golden yellow; the lateral one and venter are cream-colored.

ACKNOWLEDGMENTS



I would like to thank Jonathan A. Campbell for permission to report upon these specimens and for the loan of a slide of one of them. I am also indebted to S. K. Dutta and Joseph T. Collins for the loan of material in the collections of the University of Kansas Museum of Natural History (KU).

CORRECTION OF THE TYPE-LOCALITY OF *Phrynosoma coronatum schmidti*

The supposed occurrence of *Phrynosoma coronatum schmidti* on Cedros Island, Baja California, Mexico (Barbour 1921), has long been an enigma, because *P. cerroense* is the only horned lizard confirmed from this island (Reeve 1952). Previous authors tried to solve this dilemma by calling all Cedros Island horned lizards *P. cerroense* (Van Denburgh 1922) or *P. coronatum* (Linsdale 1932). Because *P. cerroense* is distinct from *P. coronatum* on the basis of scalation and osteological characters (Reeve 1952; Presch 1969), these explanations are not tenable. Banta (1968) was the first person to question the presence of *P. c. schmidti* on Cedros Island.

Only five specimens of *Phrynosoma cerroense* are present in U.S.A. collections. These lizards were taken on Cedros Island between 1881 and 1976. No specimens of *P. coronatum schmidti* have been collected on Cedros Island except the four type specimens collected by Wilmont W. Brown, Jr., on "Cerros Island" in 1906 (Barbour 1921). Examination of many letters and a manuscript by Brown (Archives of the Museum of Comparative Zoology, Harvard University (MCZ)), and supporting publications (Thayer and Bangs 1907a, 1907b, 1908; Thayer 1909; Nelson 1921) indicate that Brown collected many birds and miscellaneous other natural history specimens throughout Baja California during 1906-1910 for the John Elliot Thayer Museum of Lancaster, Massachusetts. Brown's herpetological collection is now housed at the MCZ. According to Brown's manuscript (no date) and itinerary (Thayer and Bangs 1907a), Brown collected "five species of lizards" on Cedros Island from March 26 to April 24, 1906 and captured no lizards on neighboring San Benito and Natividad Islands. According to MCZ catalogues, three *Sceloporus rufidorsum*, one *Uta concinna*, and four *Phrynosoma schmidti* derive from Cedros Island and two *Uta stellata* from San Benito Island. The mismatch of actual specimen data and Brown's manuscript suggests confusion; this and the absence of *P. c. schmidti* in all other known herpetological collections from Cedros Island suggests that the MCZ *P. c. schmidti* specimens are mislabeled with regard to locality. Since Brown collected extensively on the adjacent Baja California mainland, the horned lizards were probably captured from a locality within the known distribution of *P. c. schmidti*. Brown only visited two localities within the *schmidti* distribution (Jennings 1985): San Quintín and El Rosario. Comparison of specimens from the San Quintín (N=20) and El Rosario (N=5) areas with the holotype (MCZ 15142) and paratypes (MCZ 15144-45; AMNH 20583) of *P. c. schmidti* demonstrates the type series most likely derived from San Quintin because of the well developed second lateral row of fringe scales and dark dorsal pattern of the San Quintin specimens. Thus, the type-locality of *P. c. schmidti* is re-designated as San Quintín, Baja California. The probable date of collection is July, 1906, based on Brown's itinerary (Nelson 1921) and the presence of a hatchling (24 mm SVL) (MCZ 15145) in the type series.

ACKNOWLEDGMENTS

I would like to thank J. Berrian, G. Pregill, J. Rosado, J. Vindum, and R. Zweifel for the loan of specimens under their care. The MCZ Archives Librarian A. Blum graciously allowed me to quote material from copies of Wilmont Brown's unpublished manuscript and letters. Special thanks to to H. Smith and two anonymous reviewers who greatly improved the quality of the manuscript.

Plectrohyla matudai HARTWEG AND *Norops petersi* (BOCOURT): ADDITIONS TO THE HERPETOFAUNA OF HONDURAS

Wilson (1983) recently listed the members of the known herpetofauna of Honduras. In July 1983, we collected specimens of two species heretofore unknown from the country. Both were collected in the vicinity of the village of Quebrada Grande, located below the peak of Cerro Azul (15° 05' N, 88° 55' W) in the department of Copán.

On 17-19 July we collected both adults and tadpoles (KU 195447-54) of the hylid frog *Plectrohyla matudai* Hartweg, 1941, at 1370 m alongside a small stream and associated seepage area on a hill above the village. The stream lies on the border between a cattle pasture (formerly cloud forest) and disturbed cloud forest (Lower Montane Wet Forest formation; see map in Meyer and Wilson 1971). Adult males were found calling on low bushes and on the ground along the stream and tadpoles in the slow-moving water. Anuran associates included an undescribed species of red-eyed *Hyla*, *Plectrohyla guatemalensis*, and *Ptychohyla spinipollex*. Tadpoles of *P. guatemalensis* and *P. spinpollex* were collected in association with those of *P. matudai*. Macro- and microhabitat were as described for *P. matudai* by Duellman (1970), who noted this species' occurrence "along small streams and rivulets."

The coloration of an adult male (KU 195448) was as follows: dorsum dirty mustard yellow with scattering of small pale green spots; upper portion of limbs colored as dorsum; side of body golden yellow with black spotting; iris copper; venter pale gray.

Duellman (1970) gave the distribution of *P. matudai* as "elevations of 1000 to 2300 meters on the Pacific slopes of the Sierra Madre from extreme eastern Oaxaca, Mexico, to central Guatemala . . . ." He further noted that "this species also is known from the Grijalva depression in western Guatemala and from the Las Nubes block in central Guatemala." Our specimens represent a new record for Honduras, the easternmost record for the species, and a Caribbean slope record for this largely Pacific versant form. The Honduran locality is about 180 km ENE of the nearest Guatemalan record (Duellman 1970).

On 20 July 1983 a specimen of *Norops petersi* (Bocourt), 1873 (KU 195463) was delivered to us by a local villager. The locality is the same as that for *P. matudai*. The anole was collected on the edge of a corn field carved from cloud forest just below undisturbed vegetation of the same type on the slopes of Cerro Azul. The elevation is about 1400 meters.

The specimen is an adult female with a snout-vent length of 110.6 mm. The color in life was as follows: middorsum olive green, marbled with black and pale olive green grading to pale olive green on the sides with black and pale green marbling; head olive green

THE STAFF OF AESCULAPIUS

SINGLE SERPENT ENDORSED BY UNIVERSITY OF ROCHESTER N.Y. TIMES, 10-1-85.

SERPENTS give good fortune to those caring for them - ***EGYPTIANS***; endowed ***AESCULAPIUS*** with wisdom; are guardians of the springs of life and immortality - ***CARL GUSTAV JUNG***, Swiss psychologist (1875-1961); are a symbol of universal energy ***AMER. INDIANS*** and ***EAST INDIANS***; recall the basic, ***BIBLICAL*** symbol of the Tree of Life circled by a snake.

Available in beautiful 4⅝" pure 24 carat goldplate on bronze - $175; Electro-quadruple silverplate on bronze $149; With Western Red Cedar box, velvet-lined - 7¼" long by 4", 4". $50 deposit required; Balance C.O.D., UPS, allow 3-4 weeks for delivery.

Turquoise patina on bronze - $89. With box described above, $30 additional. Allow 1-2 weeks for delivery.

above with black marbling; side of head pale yellowish green with black marbling; tail with indistinct bands of olive gray marbled with black, separated by pale greenish gray; front limbs olive green, mottled with black; hind limbs pale olive-green mottled with black, separated by bands of pale olive-green; venter very pale green mottled with olive brown; dewlap pale greenish yellow with black spots.

The locals term this lizard *charancaco tigre.*

Stuart (1963) described the range of *Norops petersi* as "moderate elevations along the Caribbean versant from San Luis Potosi, Mexico, and on the Pacific from the Isthmus of Tehuantepec, Mexico, south to Honduras." Neither Meyer and Wilson (1973) nor Wilson (1983), however, listed the species for Honduras. The Honduran locality is about 130 km ESE of the nearest Guatemalan locality (Stuart 1948).

We follow Savage and Talbot (1978) in the use of the generic name *Norops* for this giant anole.

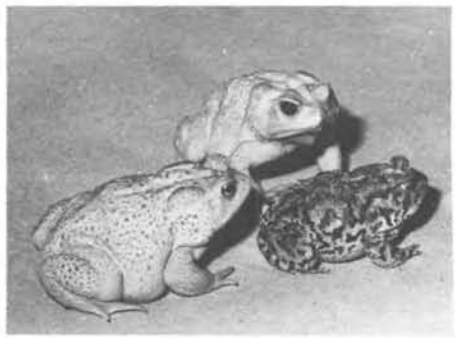
LIFE HISTORY NOTES



LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

ANURA

BUFO HOUSTONENSIS (Houston Toad). **COLORATION.** On 16 March 1984, 120 Houston toad eggs were collected from a shallow pond in Bastrop County, Texas (Houston Zoological Gardens (HZG) study site C). These eggs were taken to the HZG as part of an ongoing conservation project. Fifty of the eggs were maintained at the HZG. The remaining eggs were cultured, and the tadpoles were raised through metamorphosis, then released at study sites at Attwater Prairie Chicken National Wildlife Reserve. After the eggs at the zoo hatched and metamorphosis was complete, we observed that two of the immature toads (ca. 25mm SUL at that time) were dorsally beige in color, which is lighter than the normal brown to black coloration. An ontogenetic color change to grey-white was seen, and one toad's eyes changed from black to pink, while the other's changed from black to yellow-gold (Fig. 1). Both toads, now adults (ca. 60 mm SUL), have no other apparent abnormalities and appear to be growing at a normal rate. Upon their deaths, the toads will be deposited in the vertebrate collection at Texas A&M University.

Financial support for this research was provided by the United States Department of Interior, Fish and Wildlife Service, Office of Endangered Species, and the Zoological Society of Houston. Appreciation is also acknowledged to the Texas Parks & Wildlife Department and the U.S. Fish and Wildlife Service for supplying permits.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). **COEXISTENCE.** Blair (1936. Copeia 1936:115) was the first to note the sharing of burrows of *Microhyla (= Gastrophryne) olivacea* with tarantulas *(Dugesiella hentzi)* from Tulsa Co., Oklahoma. Similar relationships have been reported in north-central Texas (Hunt 1982. Texas Parks and Wildlife 40:12-14). Freiberg (1951. Trans. Kans. Acad. Sci. 54:374-386) listed the following animal associates found under rocks and logs with *G. olivacea:* various invertebrates, *Acris crepitans, Bufo terrestris, Rana pipiens, Eumeces fasciatus, E. obsoletus* and *Scalopus aquaticus.* Here, we report the first documented instance of *G. olivacea* coexisting with Eastern collared lizards *(Crotaphytus collaris collaris).*

On 26 May 1985 in Somervell Co., Texas, 12.4 km NE of Glen Rose off U.S. 67 on county rd. 406, an adult *G. olivacea* (head-body length = 26 mm, tibia length = 10 mm) was found in a burrow beneath a large (61 X 51 X 20 cm) limestone rock coinhabited by an adult male and female *C. c. collaris.* Immediately upon turning over the rock shelter, the disturbed collared lizards escaped into *Juniperus ashei* debris while the *G. olivacea* remained in its retreat. After collecting the toad, the rock was carefully put back in its original position. Following a waiting period of ca. 20 minutes, we overturned the rock and found that both lizards had returned. One of us (CTM) visited the site 41 days later (6 July 1985) and noted, presumably, the same male *C. c. collaris* under the rock. Evidently, this particular rock shelter is a primary retreat in the home range of these collared lizards.

The significance, if any, of this incidental association is unknown. Collared lizards are a very aggressive and highly territorial species and do not normally tolerate others near or in their retreats.

Blair (op. cit.) reported that *G. olivacea* may benefit from protection against summer heat and drought and possibly against predation in the presence of tarantulas. In addition, Hunt (op. cit.) suggested a similar theory after observing an encounter of a *Thamnophis proximus* being attacked by a seemingly protective tarantula. Interestingly, the noxious and irritating skin secretion of the eastern narrowmouth toad *(G. carolinensis)* has been noted to be protective against some predators (Anderson 1954. Tulane Stud. Zool. Bot. 2:15-46); however, *Agkistrodon contortrix* (Anderson 1942. Bull. Chicago Acad. Sci. 6:203-220), *Nerodia sipedon* (Fitch 1956. Univ. Kans. Mus. Nat. Hist. Misc. Publ. 8:275-306) and *T. sirtalis* (Fitch 1965. Ibid. 15:493-564) will prey on *G. olivacea.* Garton and Mushinsky (1979. Can. J. Zool. 57:1965-1973) suggested that *Gastrophryne* spp. benefit from their toxicity in evolving a response to the swarming attack of their preferred prey (ants) and in the avoidance of predators ("toxic phenotypes").

The *G. olivacea* is deposited in the Arkansas State University Museum of Zoology (ASUMZ 4644).

We thank Mr. Jim Riddle for allowing us access to his property. We also acknowledge Drs. Henry R. Mushinsky and Hobart M. Smith for technical assistance. Finally, we thank Drs. H. M. Smith and Stanley E. Trauth for critically reviewing this note.

PHRYNOHYAS VENULOSA (Veined treefrog). **FOOD.** The known biology of this treefrog is largely summarized in Duellman (1970. Monogr. Mus. Nat. Hist., Univ. Kansas No. 1, vol. 1). In that work and other primary literature that we searched there was no mention of food habits.

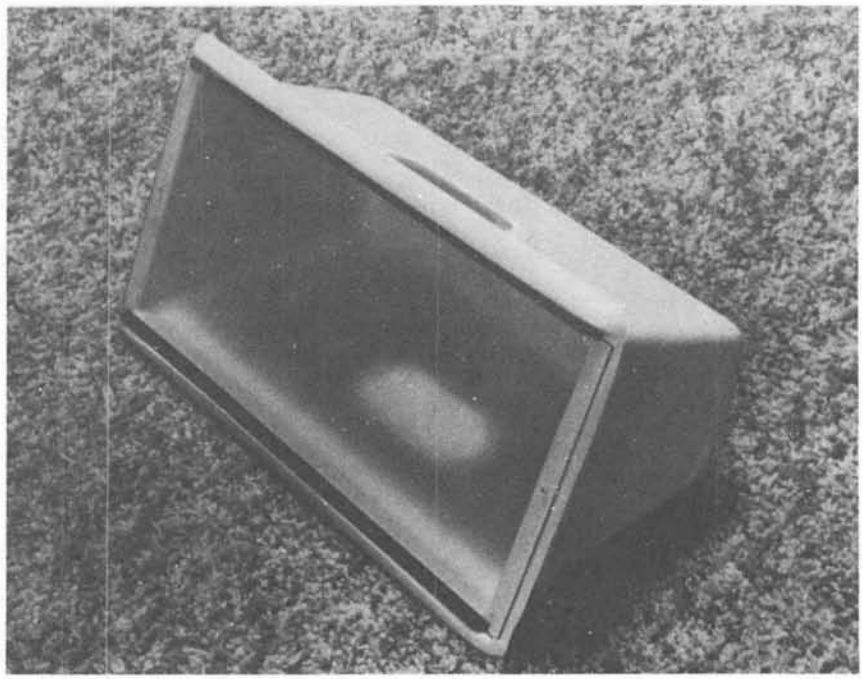
On the night of 28 October 1984 we found a 60 mm S-V *Phrynohyas venulosa* on a road 12 km N Chunchucmil, Yucatán, México that had a 30 mm S-V *Hypopachus variolosus* (sheep frog) in its mouth; only the hind limbs of the *Hypopachus* were visible. The *Hypopachus* was still alive when removed from the *Phrynohyas.* Whether this was a deliberate act of eating the smaller frog or an accidental ingestion resulting from the two frogs simultaneously grabbing the same prey could not be determined, but the only other material in the *Phrynohyas* was some dead microphyll leaves in the mouth and stomach, and the *Hypopachus* alimentary tract contained only a few partially digested ants. The *Phrynohyas* showed no ill effects from the supposedly toxic skin secretions of the *Hypopachus.* We subsequently examined over 70 stomachs of Mexican *P. venulosa* from six different states and the contents were entirely arthropod, particularly the insects, including Orthoptera (crickets and unidet.), Coleoptera (Coccinellidae, Chrysomelidae, Elateridae, Scarabaeidae, and unident.), Diptera, and Homoptera (Cercopidae); a few spiders also were found. Most stomachs were empty.

Submitted by **HAROLD A. DUNDEE,** Department of Biology, Tulane University, New Orleans, Louisiana 70118 and **ERNEST A. LINER,** 310 Malibou Boulevard, Houma, Louisiana 70364, U.S.A. ●

PHRYNOHYAS VENULOSA (Veined treefrog). **REPRODUCTION AND SIZE.** The latest breeding date that has been reported is 3 Aug. (McDiarmid 1968. L.A. County Mus. Contrib. Sci. 134) in Sinaloa, México. On 2 Sept. 1962 Dundee collected three males that were uttering songs (Grrraaack) from trees along the Tuxpan River at Tuxpan, Vera Cruz, México. Also taken at that time were 10 females. The male (56-69 mm S-V, $\bar{X}$ = 63.7) and female (56-68 mm S-V, $\bar{X}$ = 58.1) averages are equal to or smaller than the smallest aggregated animals reported (63.7 mm S-V for 13 males and 63.5 for 14 females; McDiarmid 1968, op. cit.). None of our females, however, though near the singing males, contained mature ova. One might speculate that size of breeding animals varies with time of year.

Submitted by **HAROLD A. DUNDEE,** Department of Biology, Tulane University, New Orleans, Louisiana 70118 and **ERNEST A. LINER,** 310 Malibou Boulevard, Houma, Louisiana 70364, U.S.A. ●

RANA CATESBEIANA (Bullfrog). **FOOD.** *Rana catesbeiana* are known to prey on other anurans (Korschgen and Moyle 1956. Amer. Midl. Nat. 54:332-341; Smith 1973. Ph.D. dissertation, Univ. Kansas, 206 pp.; Corse and Metter 1980. J. Herpetol. 14:231-238). However, only Holman (1957. Copeia 229) reported bullfrog predation on a spadefoot toad, when he recorded *Scaphiopus holbrooki* as prey. This note records a western spadefoot, *S. hammondi,* as bullfrog prey.



At 0130 h on 4 March 1978, we collected an adult (SVL = 141 mm) male *R. catesbeiana* crossing Cherokee Road ca. 50 m east of its juncture with Thompson Flat Road, Butte County, California. Dissection of the male's stomach revealed an adult (SVL = ca. 60 mm) female *S. hammondi,* apparently recently swallowed because evidence of digestion was not yet detectable by examination of the skin of the toad. *R. catesbeiana* are locally abundant and move overland during spring rains warm enough to allow activity since over one hundred *R. catesbeiana* had been observed on roads in the general vicinity over the previous three hours. During that time there had been a consistent soft rain and wet substrate temperatures exceeding 10° C (the collection site substrate temperature was 11° C). *S. hammondi* may be cued into surface activity by rains (Dimmitt and Ruibal 1980. J. Herpetol. 14:21-29), so they may fall prey to *R. catesbeiana* that exhibit overland movements under the same conditions.

The female *S. hammondii* is deposited in the Los Angeles County Museum of Natural History (LACM 136709).

RANA SYLVATICA (Wood Frog). **PREDATION.** On 12 April 1984 I noted many caddisfly (Tricoptera) larvae crawling on submerged vegetation, *Rana sylvatica* egg masses, and the bottom of a temporary pond in the Sandyston Township, Sussex County, New Jersey portion of the Delaware Water Gap National Recreation Area. Some of the larvae appeared to be attempting to break through the gelatinous envelopes encasing the eggs, but certainty was impossible due to the surface motion of the water and the fact that most egg masses were 30 cm or more away. I collected a gallon of pond water with

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

two of the smaller egg masses and four caddisfly larvae and took them to the New Jersey State Museum for further observation.

All of the larvae were actively crawling about in the container and over the egg masses the next day and were observed at 15 to 30 minute intervals. They frequently tugged at the gelatin with their front pairs of legs but did not break through. Whether it was a deliberate attempt to reach the eggs or only their method of maintaining footholds on the jelly-like surfaces remains uncertain. Seven hours passed before it was witnessed by science bureau staff member Shirley Albright and myself that one of the caddisfly larvae had actually penetrated a portion of an envelope and was in the process of devouring a *R. sylvatica* egg. About one-third of the egg was eaten, after which the larva resumed its scurrying about in the container.

The following day I noted that six more eggs had been partially eaten from a mass containing 143 eggs and portions of three from a mass of 147 were also devoured. However, the water temperature had risen to 24° C, a 13° C increase since its removal from the pond. Two of the larvae died and the other two appeared near death, probably due to this increase in water temperature and a decrease in dissolved oxygen. It must be noted that no food (except the frog eggs) had been provided for the larvae and that it is not known if the *R. sylvatica* eggs were alive or dead when eaten. Although the restrictive conditions in the container may have contributed to the larvae's behavior, the observation is nevertheless noteworthy, inasmuch as I know of no other records of caddisfly larvae preying or scavenging on amphibian eggs.

The larvae were preserved and identified as members of the genus *Limnephilus*, a group that contains a hundred or more species of climbers, sprawlers and clingers which inhabit all types of lotic and lentic habitats, including temporary ponds. Their distribution is widespread in the northern portions of North America.

I am grateful to William Wolfe, Rutgers University, and Gunther Schuster, Eastern Kentucky University, for assistance in identification of the caddisfly larvae and to the administration and staff of the Delaware Water Gap National Recreation Area for logistic support and permission to work at the site.

CAUDATA

PLETHODON VANDYKEI IDAHOENSIS (Coeur d' Alene Salamander). **PREDATION.** On 13 July 1985 at 0735 Mountain Daylight Time (approximately 1.5 hr after sunrise) we observed an American Robin *(Turdus migratorius)* capture and partly consume a Coeur d' Alene Salamander *(Plethodon vandykei idahoensis)*. The incident occurred during a continuing study of the foraging behavior of *P. v. idahoensis* in Lincoln Co., Montana. Predation upon this salamander has not previously been reported (see Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University Press of Idaho).

The robin was first seen alighting approximately 3 m up a vertical, moss-covered cliff where we had earlier been observing nocturnal salamander activity. We saw the bird snatch an object from the moss and carry it to the base of the cliff. On the ground, the bird thrashed and pecked at the object for about 20 sec when it was frightened away by our approach. We then discovered that the robin had captured an adult male salamander of 4.48 cm SVL. The salamander had lost approximately half of its tail, which we assume was eaten by the robin. The only other marks on the salamander were two impressions, presumably made by the bird's beak, 0.40 cm anterior to the tail breakage. The salamander was collected and lived for two days, apparently dying of internal injuries. It will be deposited in the Amphibian Collection of the Department of Zoology at Washington State University, Pullman.

SERPENTES

DIADOPHIS PUNCTATUS PUNCTATUS (Southern Ringneck Snake). **SIZE.** An exceptionally large *Diadophis punctatus punctatus* was caught by Martin Nowak on 14 April 1985 as it was crossing a road at 2130 h during a warm rain in eastern Jefferson County, Alabama (T15S, R1W, Sec. 26). The snake, a gravid female, had a total length of 482 mm (396 mm SVL, 86 mm TL) and a mass of 20.2 g. The record length for *D. p. punctalis* is listed as 470 mm by Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). Mount (1975. The Reptiles and Amphibians of Alabama, Auburn Univ. Agricultural Experiment Station, Auburn) reported *D. p. punctatus* attains a maximum total length of approximately 445 mm in Alabama.

The new record specimen has been deposited in the University of Alabama at Birmingham Vertebrate Museum (VM-UAB 0384).

Submitted by **KEN R. MARION,** Biology Department, and **MARTIN C. NOWAK,** Hospital Administration, University of Alabama at Birmingham, Birmingham, Alabama 35294, U.S.A. ●

DISPHOLIDUS TYPUS (Boomslang). **BEHAVIOR.** When threatened, *Dispholidus typus* usually responds by cylindrical inflation of the neck and anterior half of the body, as described by several authors (see Broadley 1983. Fitzsimons' Snakes of Southern Africa, Delta Books). Another method of defense is detailed here.

On 23 February 1985 in an area of tree savanna approximately 1 km north of Moeding College, Otse, Botswana (25.02 S: 25.45 E), a brown female boomslang (1.25 m TL) was observed resting on the ground under a bush at 0910 h. The snake was seized with a grabstick and responded by inflating its body in the manner previously described, and striking. It then pulled free from the grabstick and fled through the bush. About 20 sec later, the snake was observed some 6 m away, lying totally motionless on a patch of open ground, with its body kinked in such a manner as to resemble a stick, several of which were lying on the ground nearby. The snake remained motionless in this position until a press stick was placed on its neck, whereupon it again struck and attempted to inflate its body.

Psammophis and *Thelotornis* are known to mimic branches in attempts to conceal themselves, but such behavior is usually observed in trees, not on the ground.

The snake is at present alive and will be deposited in the National Museum, Bulawayo, Zimbabwe.

Submitted by **STEPHEN SPAWLS,** Moeding College, Private Bag 11, Lobatse, Botswana. ●

HETERODON PLATYRHINOS (Eastern Hognose Snake). **BEHAVIOR.** Assateague Island is a narrow 37-mile long barrier island located along the coasts of Maryland and Virginia. *H. platyrhinos* is the most common species of snake found there, where it apparently thrives on the abundant *Bufo woodhousei fowleri*. While the presence of *H. platyrhinos* on barrier islands and in similar saline environments is well documented, there appear to be few if any records of this species spending time in sea water.

During the hot summer and fall months, *H. platyrhinos* is frequently observed resting on the Assateague beach just above the reach of breaking waves, or swimming in the breakers a few feet beyond the swash zone. The snakes have been seen spending up to five minutes in the water, usually swimming parallel to shore. They exit the water by "body surfing" on an incoming wave, and are left on the beach as the wave recedes. Entrance into the surf does not appear to be the result of the presence of an observer, and no feeding or activity other than swimming and floating has been recorded. While resting on the wet sand during hot weather may represent an attempt at thermoregulation, the advantages of entering and spending time in the surf are unclear.

NERODIA SIPEDON SIPEDON (Northern Water Snake). **COLORATION.** A subadult male amelanistic specimen of *Nerodia sipedon* was collected in a small remote stream in southwestern Botetourt Co., in Blue Ridge, Virginia. The snake, collected by Conny Wallace and David Jobe, was reported submerged in the stream in a sunny location at ca. 1400 h on 18 June 1983. It has a normal pattern with ground color of a light flesh tone and a pattern of slightly darker flesh tone. The ventral side is mostly white and the eyes are a

pinkish brown color. The small dark patches on the head and body are assumed to be indications of pigment retention.

At the time of capture the snake measured 558 mm total length and 427 mm s-v length with an incomplete tail of 131 mm. In a recent publication of albinism (Dyrkacz 1981. Recent Instances of Albinism in North American Amphibians and Reptiles. SSAR Herp. Circ. 11:22p), E. J. Maruska reported a juvenile albino *Nerodia sipedon* from Marion, IN. Another incidence of albinism in *Nerodia* was reported by Freed (1983. Herp. Review. 14). The snake is currently being maintained in the collection of David Jobes.

Submitted by **LYNN D. ROBERTSON,** Rt. 1 Box 346, Roanoke, Virginia 24012, U.S.A. ●

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **CANNIBALISM.** Ophiophagy is common in some snake genera (e.g. *Lampropeltis*) but in others, its occurrence is rare or unreported (Polis and Myers 1985. J. Herpet. 19:99-107). Stomach contents often serve as the primary evidence for this feeding behavior. In *Thamnophis sirtalis* very low frequencies of ophidian prey, including conspecifics, have been found in stomach contents (0.37%, Fitch 1965. Univ. Kansas Publ. Mus. Nat. Hist. 15:493-564), but the problem with such data is in determining how the snakes came to be ingested. They may have been dead when encountered or one snake may have been swallowed while competing with another for the same food item (Genter 1984. Herp. Review 15(2):49-50). It is also possible that these cases of ophiophagy were the result of an active attack by one snake on another. Here I report such a conspecific attack.

Neonate *T. s. sirtalis* were obtained from four litters born in captivity on 17-19 September 1984 to recently collected females from Wayne County, Michigan. A total of 28 (6,6,8,8) neonates were housed in a large (1 m dia.) round enclosure with a pea-gravel substrate, 6 (16 cm dia.) circular cover objects, and water dishes, on a 12:12 LD cycle. The activities of the animals were continually recorded with a low-light slow-motion video system. The animals were being studied as part of a research program on conspecific aggregation and had not been fed at the time of the incident reported here.

On 29 September 1984 at 1644 h EST, one of the snakes (Snake A: female, 133 mm SVL, 159 mm total length, 1.57 g mass) was observed attacking another new-born (Snake B: unidentified), grasping it in the middle of the body. The two snakes struggled for about four minutes before separating. Within three minutes there was a second attack by snake A. This time the bite was directed towards the head of a third unrelated snake (Snake C: male, 134 mm SVL, 171 mm total length, 1.97 g mass). This attack was considerably shorter (30 secs.), and ended with the release of snake C which quickly moved away. Within four minutes snake A began to follow closely the trail of snake C. It was not possible to observe tongue flicking. After a brief pause, it once again grasped the other snake by the head. Snake C again responded by rapidly twisting its body. The struggle continued for 48 min, with ingestion lasting more than four hours, at which time the half-consumed male was discovered and removed.

These observations indicate that in *T. s. sirtalis*, a species not known for its ophiophagous activities, cannibalism may involve the active pursuit and attack by conspecifics.

G. M. Burghardt, B. C. Bock and C. L. Sagers made helpful comments on the manuscript. The work was supported by NSF grant BNS-8217509 to GMB.

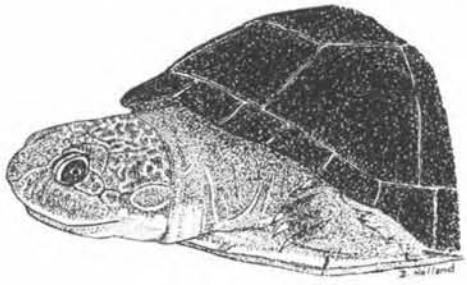
SAURIA

IGUANA IGUANA (Green Iguana). **TERRESTRIALITY.** In June 1982 researchers at Hato Masaguaral, about 50 km SSW of Calabozo, Guarico, Venezuela, led us to an abandoned, seasonally-inundated borrow pit (on Hato Flores Moradas, 8.543° N, 67.583° W) with over one hundred burrows, used as nocturnal refuges by green iguanas. Throughout most of its range, the green iguana sleeps in trees, seeking temporary refuge in burrows only when away from water and exposed to a potential predator. Fig. 1 shows the densest group of burrows, most of which were unoccupied at any one time. More than one iguana were seen to use a single entrance.

Figure 1. Communal iguana burrows.



Approximately 20 visits over the following 1-1/2 years revealed that these iguanas had greater flight distances (>80 m) than their adjacent arboreal conspecifics (20-60 m), perhaps because the burrow-living iguanas were more vulnerable to mammalian predators. An apparent decrease in the numbers of the terrestrially-refuging iguanas followed a period when a grison *(Grison vittata)*, a burrowing mustelid, frequented the area (as indicated by tracks, sightings, and several partially-consumed iguana carcasses).

One isolated burrow was excavated, beginning at its 20 X 20 cm entrance in a small bank 50 cm below the surrounding, level terrain. The burrow's single horizontal passage, gradually became narrower (10 X 15 cm) to a bend of about 30° 1.7 m from the entrance. At 2.5 m from the entrance the passage became slightly larger (20 X 20 cm), turned 90° and gradually ascended, until a loose plug of soil separated the passage from the surface, about 4.5 m from the entrance. *Iguana* feces were found at the end of the burrow. We saw evidence that the iguanas modified their burrows, but we did not witness any being constructed. Female iguanas excavate nest burrows, but these are ordinarily shorter and sharply downward-sloping, ending 1-2 m underground.

Burrow-refuging iguanas were seen at sites away from trees further west on Hato Masaguaral (8.56° N, 67.65° W) and in road banks on Hato El Frio, Estado Apure (7.77° N, 68.91° W).

Iguanas are known to live among rocks when deprived of trees by human activities (Roze 1956. *In:* El Archipielago de Los Roques y La Orchila. Sociedad de Ciencia Naturales La Salle. Caracas.), but the burrows photographed here were occupied voluntarily, as numerous suitable trees surrounded the borrow pit.

TESTUDINES

CLEMMYS MARMORATA (Western Pond Turtle). **FEEDING.** Neustophagia (modified filter feeding) on small aquatic invertebrates has been noted in the turtles *Podocnemis unifilis* and *Chrysemys picta* (Belkin and Gans 1968. Ecology 49:768-769) and *Emydura* sp. (Legler 1976. Vict. Nat. 93:40-43). Herein I report on the occurrence of this mode of feeding in the Western pond turtle *(Clemmys marmorata)*.

On 23 and 24 July 1981, I observed three adult *C. marmorata* ca. 130-150 mm CL feeding on cladocerans at Pico Pond, San Luis Obispo County, California. Each turtle moved with the body just below (1-2 cm) the surface. Short thrusts (10-15 mm) of the head broke the surface, such that the eyes and maxilla were exposed. Distensions of the pharyngeal region were clearly visible from a distance of less than 2 m. A small volume (est. 0.5 ml) of water was occasionally noted to be ejected through the nares. One animal was observed to make 19 feeding movements in one min, and another was noted to make 79 movements in five min. A small bubble (ca. 6-8 mm dia.) was left at the surface after each movement. This behavior persisted for the duration of the period of observation (ca. 30 min), and was confined to an area of 3 m^2 near the observation blind free of emergent vegetation (*Scirpus* sp.).

Stomach flushings (Legler 1977. Herpetologica 33: 281-284) of these individuals produced up to 2 cc (containing several hundred

individuals) of *Daphnia* sp. Feeding on this temporarily abundant resource appeared to be preferential, as the turtles noted contained only these prey items. Additional samples from other animals taken concurrently produced typical prey (Chironomid and Odonatan larvae).

Submitted by **DAN C. HOLLAND,** Department of Biology, California State University-Fresno, Fresno, California 93740, U.S.A. (Current Address: Department of Biology, University of Louisiana, Lafayette, Louisiana 70504, U.S.A.) ●

PSEUDEMYS SCRIPTA ELEGANS (Red-eared Slider) **BEHAVIOR.** Kramer (1984. Herp. Review 15(4):113-114.) reported an instance of unusual behavior in *Pseudemys nelsoni*. The present article reports on similar behavior in a captive colony of *Pseudemys scripta elegans* at the Sedgwick County Zoo (SCZ), Wichita, Kansas.

The colony consists of 15 females and five male adult specimens of this taxon and all have been in the SCZ collection for at least two years. They are maintained in a large display unit which is partially aquatic, partially terrestrial. The animals are housed with *Chrysemys picta belli, Pseudemys floridana hoyi, Trionyx spiniferus hartwegi,* and *Chelydra serpentina*. The *P. s. elegans* rarely if ever interact with their cagemates.

Of the group of red-eared sliders, two males are dominant over all others and are the primary courters and only successful breeders. In the spring (March—mid-May) of 1985, these two individuals were observed to display behavior similar to that described for *P. nelsoni*. They were seen to approach subordinate females and align themselves anterior to and facing these females. The males assumed a "fighting bull" posture typical of courting *P. s. elegans:* head withdrawn, hindquarters raised, scraping the substrate with alternate forelimbs. Approached females were quiet. They withdrew their limbs but constantly faced the attending males. Occasionally, these approached females would extend their heads and necks as if to investigate an attending male. At this moment, the male would immediately bite and hold firmly onto the nape of the female's neck. The bitten female would then swim off frantically and attempt to dislodge the male. After 3-7 minutes, the female would become quiescent and sink to the bottom of the exhibit.

Both animals remained quiet for several minutes whereupon the male began violently ramming his shell into the female's carapace by extending and retracting his neck while retaining his bite hold. This ramming was repeated 7-15 times over 3-5 seconds. The pair typically would then remain quiet for several minutes before another ramming bout began. Anywhere between 5-10 ramming bouts were observed in any given session.

These ramming bouts were distinctly audible and could be felt through the concrete floor outside the exhibit. Normally, after 15-20 minutes, the female would make another effort to dislodge the male, usually successfully. If the effort to dislodge the male was unsuccessful, further, less intense ramming bouts occurred until the female dislodged the male. Males have not been observed to release their holds voluntarily.

Interestingly, this behavior is directed only at subordinate females. The dominant male *P. s. elegans* do interact aggressively with subordinate males but this behavior consists only of chasing and biting shell margins. Non-subordinate females react to aggressive males by returning bites and swimming away. Of the 15 females in the group, seven bear nape scars, evidence of past biting/ramming bouts. Non-subordinate females have no scars.

It is unknown whether this behavior is an artifact of captivity, possibly due to overcrowded conditions. Kramer's and Jackson and Davis' (1972. Herpetologica 28:58-64) observations suggest that this behavior is natural and possibly widespread in *Pseudemys*. My observations also suggest that the behavior is not related to courtship but rather is part of establishing a social hierarchy, at least in captivity.

Submitted by **ERIC M. RUNDQUIST,** Department of Herpetology, Sedgwick County Zoo, Wichita, Kansas 67213, U.S.A.●

PSEUDEMYS SCRIPTA ELEGANS (Red-eared Slider) **DEFORMITY.** An adult female *Pseudemys scripta elegans* was collected by a motorist on a road in or near Houston, Harris Co., TX, during the third week of June 1983 and was brought to the Houston Zoological Gardens on 21 June 1983. The central portion of both the carapace and plastron were constricted transversely at mid-body, giving the shell a figure-eight like appearance (Figure 1). A nylon band measuring 6.2 mm wide and 265 mm in circumference was removed from the area of constriction and was apparently the cause of this gross deformity. The band probably became lodged at mid-body when the turtle was a juvenile, preventing the growth of the central portion of the shell. Considering the central location and the non-elastic properties of the band, it is likely that it had been placed around the turtle deliberately. This man-made deformity (either accidental or on purpose) is notable because of its severity and minimal effect on the general health of the turtle.

Shell measurements of this specimen are: Carapace L = 235 mm, plastron L = 215 mm, height anteriorly = 97 mm, height posteriorly = 97 mm, width anteriorly = 170 mm, width posteriorly = 164 mm, constriction height = 70 mm, constriction width = 95 mm. Width and height measurements were taken at the location of their maximum values.

I thank Paul S. Freed for the photo used in Figure one.

ANOTHER REASON FOR HERPETOLOGISTS TO PICK UP THEIR BEER CANS. An adult *Nerodia sipedon*, found along the Flint River, Macon Co., Georgia. The snake appears to have been searching for small fish (known to enter such containers) and when it tried to pull its head out of the can it became helplessly trapped by the inner part of the top and drowned in ca. 1 m of water. (Submitted by Bob Herrington, Department of Zoology, Washington State University, Pullman, Washington). ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION

AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

REPTILE CAGES

Designed with your needs in mind.

Desirable features of Herp-Huts:

- Should never have to be replaced.
- Molded in one piece of durable fiberglass, no seams, all corners rounded.
- Smooth finish facilitates easy cleaning and sterilization.
- Top front ridge, ideal for clamping heat lamp, if desired.
- Two vented louvers per cage (standard), designed to prevent scratches to animals and entrance of flies. Side or top mount possible.
- Side mounted vent plates make top/bottom interchangeable, creating pitch alternatives.
- Sloping front for easy viewing.
- Special vertical ridges on either side of cages "A" & "B" minimize possibility of small snakes getting wedged or escaping.
- Design suitable for reptile houses, mobile reptile exhibits, and reserve cages.
- ★ **Newest Option:** Feature requested - Hingeable front door with or without 5 inch safety glass shield.
- Traditional sliding glass front accessibity.

A New Approach to an Old Concept

Herp - Huts currently available in four standard sizes and colors: Blue, Aqua, Beige, White

Pictured:

Cage A: 16¼" W X 7½" H X 6¼" D $35.00
Cage B: 22¼" W X 9¾" H X 11" D $45.00
Cage C: 30¾" W X 16" H X 17¾" D $90.00
Cage D: 42½" W X 19¾" H X 24" D $125.00

Current Prices w/out front glass

New county records (Dellinger and Black 1938. Occ. Pap. Univ. Arkansas Mus. 1:1-47; Dowling 1957. Occ. Pap. Univ. Arkansas Mus. 3:1-51). Craighead County specimen represents the first record from Crowley's Ridge (an alluvial ridge) and extends known range into the deltaic region of eastern Arkansas (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston).

Submitted by **STANLEY E. TRAUTH,** Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467, U.S.A. ●

SERPENTES

DIADOPHIS PUNCTATUS ACRICUS (Key Ringneck Snake). USA: FLORIDA: Monroe Co: Little Torch Key. 15 February 1978 - mid-July 1984. James Hardiman. Museum of Comparative Zoology (MCZ 156556, 156989, 158989, and 169211). Middle Torch Key. 28 January 1980. Peter Warny. (MCZ 158990). Verified by James Lazell. First records off Big Pine Key (Ashton and Ashton 1981. Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Windward Publ., Inc., Miami. 1-176) and first definite records for tropical hardwood hammocks (Ruttenber and Weiner 1978. Florida Keys hardwood hammock atlas. Florida Keys Land Trust, Key West).

Submitted by **JAMES D. LAZELL, JR.,** The Conservation Agency, 6 Swinburne St., Jamestown, Rhode Island 02835, U.S.A. ●

HYPSIGLENA TORQUATA JANI (Texas Night Snake). USA: TEXAS: Somervell Co: 12.4 km NE Glen Rose off US 67 on County Rd. 406. 26 May 1985. C. T. McAllister. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 4643). New county record, extending the range north

from Bosque County (Raun and Gehlbach 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. No. 2), near the eastern limit of the species' range (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston).

Submitted by **CHRIS T. MCALLISTER,** Renal-Metabolic Lab (151-G), Veterans Administration Medical center, Dallas, Texas 75216 and **STEPHEN P. TABOR,** 224 S.W. Thomas Street, Burleson, Texas 76028, U.S.A. ●

NERODIA RHOMBIFERA (Diamondback Water Snake). USA: TEXAS: Collin Co: Farm Road 1377, 2.7 km S of Farm Road 75. 24 May 1985. R. Ward. Verified by R. Ward. North Texas State University Herpetological Collection (NTSUHC R-635). First record for county, helps fill distributional hiatus in the upper drainage of the Elm Fork, Trinity River (Raun and Gehlbach 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. 2).

Submitted by **ROCKY WARD,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203, U.S.A. ●

NERODIA TAXISPILOTA (Brown Water Snake). USA: GEORGIA: Habersham Co: Lake Demorest, 1.0 km E of US 441, Demorest, 420m. 15 March 1984. C. D. Camp and M. K. Tanner. Verified by C. D. Camp. University of Georgia Museum of Natural History (UGAMNH 19313). Ca. 80 km north of previously recorded locality (Camp and Howland 1983. SSAR Herp. Review 14(1):28) and highest elevation recorded for species.

Submitted by **CARLOS D. CAMP,** Biology Department, Piedmont College, Demorest, Georgia 30535, U.S.A. ●

SISTRURUS MILIARIUS STRECKERI (Western Pigmy Rattlesnake). USA: TEXAS: Sabine Co: 4.8 km N Milam at Stephen F. Austin State University Forestry Field Camp. 9 June 1979. S. P. Tabor. Verified by J. F. Scudday. Sul Ross State University (SRSU 5616). New county record; fills hiatus between Jasper, Newton (Raun and Gehlbach 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. No. 2) and San Augustine counties (Rakowitz et al. 1983. Herp. Review 14:85-89).

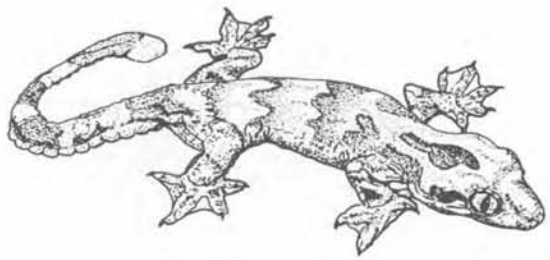
Submitted by **STEPHEN P. TABOR,** 224 S.W. Thomas Street, Burleson, Texas 76028, U.S.A. ●

THAMNOPHIS ORDINOIDES (Northwestern Garter Snake). USA: WASHINGTON: Clallam Co: Ozette Island, 1.2 km SW of Cape Alava, T31N R16W Sec. 27. 18 July 1982. K. B. Aubry. Verified by K. B. Aubry. University of Washington Burke Museum, Seattle (UWBM 91). First record from Ozette Island. This species occurs on many islands in Puget Sound (Slater 1963. Occ. Pap. Dept. Biol., Coll. Puget Sound, Tacoma 24:212-233), but has not previously been reported from islands off the Washington coast. See Aubry and West 1985. SSAR Herp. Review 16(4): 115 for island description.

Submitted by **KEITH B. AUBRY,** College of Forest Resources, AR-10, and Burke Museum, DB-10, University of Washington, Seattle, Washington 98195 and **STEPHEN D. WEST,** College of Forest Resources, AR-10, University of Washington, Seattle, Washington 98195, U.S.A. ●

TESTUDINES

CLEMMYS MARMORATA MARMORATA (Northwestern Pond Turtle). USA: CALIFORNIA: Modoc Co: Ash Creek, 2 km W Adin. 18 August 1985. L. Sinclair and J. Buskirk. Verified by Harry W. Greene. Eight individuals (juveniles and adults) were seen, photographs deposited in Museum of Vertebrate Zoology, Univ. of California, Berkeley. First record for Modoc County and easternmost record for California east of the Sierra-Cascade crest (Bury 1970. Cat. Amer. Amphib. Rept. 100.1-100.3). Extends range 100 km SE Lower Klamath Lake (California Academy of Sciences) and ca. 50 km ENE Fall River Mills (Los Angeles County Museum of Natural History).



Submitted by **JAMES R. BUSKIRK,** 4108 Howe Street, Oakland, California 94611, U.S.A. ●

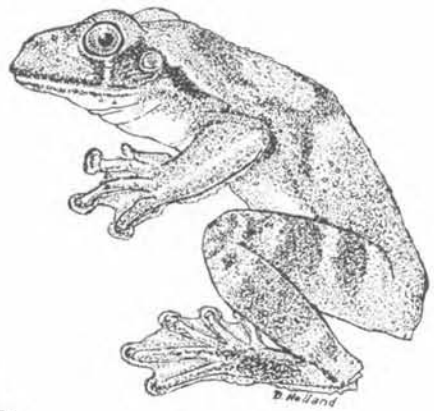
EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: WISCONSIN: Oconto Co: Pipeline Road, several hundred m south of Logan Road (T30N, R18E, Sec. 18). 2 March 1985. J. R. Hodgson and P. A. Cochran. University of Wisconsin-Madison Zoology Museum (UWZM H-22626). First record for Oconto County (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee. 205 pp.); the only other record listed by Vogt from northeastern Wisconsin is from adjacent Marinette County.

Submitted by **PHILIP A. COCHRAN** and **JAMES R. HODGSON,** Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115, U.S.A. ●

CORRIGENDUM

TESTUDINES. Clemmys muhlenbergii (1985. Herp. Review 16(1):32). The first sentence of the second paragraph should be changed to read: "We consider this the first adequately documented record of a population of this species in Massachusetts." *Ed.* ●

BOOK REVIEWS



Guide to the Amphibians and Reptiles of Fresh Water Italy (Guide per il Riconoscimento delle Specie Animali delle Acque Interne Italiane, No. 27. Anfibi, Rettili), by Benedetto Lanza. 1983. Consiglio Nazionale delle Ricerche (Ufficio Pubblicazioni), Piazalle Aldo Moro, Roma, Italy. 1-196, 72 figs. Price 9,000 Lire (about U.S. $5.00).

This is one in a series of publications about the freshwater fauna of Italy. This attractive volume is printed on high quality glossy paper trimmed to 14 X 21.5 cm and has a soft cloth binding. Although treating all of the nine species of salamanders and 19 species of anurans in Italy, only the truly aquatic or aquatic-margin reptiles are included—one turtle *(Emys orbicularis)* and three species of *Natrix*.

Seventeen pages are devoted to a general account of the structure of amphibians, and six pages are devoted to the same material on reptiles. Detailed, well-illustrated keys to the eggs, larvae, and adults of amphibians occupy 35 pages, whereas the key to the four species of reptiles is contained on one page. The remainder of the book is devoted to accounts of each of the species, with abbreviated accounts of the subspecies.

The book is extremely well illustrated with drawings of all of the species, including eggs and larvae of the amphibians, as well as skeletons of some of the taxa. This little book will be highly useful to anyone attempting to identify amphibians from Italy. Furthermore, it provides moderately detailed accounts of the structure of each of the species and illustrations of variation in color patterns.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1985

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

1986 ANNUAL MEETING

The 1986 annual meeting will take place at Southwest Missouri State University, Springfield, Missouri, 10-15 August.

SSAR members are reminded that this meeting will include the ever-popular Annual Auction of herpetologically related books and other items. It is not too early to start collecting your collectibles, forwarding them (or a statement of your intention to bring them) to meeting co-chairman:

Robert Wilkinson
Life Sciences Department
Southwest Missouri State University
Springfield, Missouri 65802, U.S.A.

David Dennis and Kraig Adler, co-producers of the "Herpetologists Then and Now" slide presentation given at past SSAR meetings, request that society members send them duplicate slides of memorable (or forgettable) herpetological happenings — and their participants — for inclusion in future presentations. Anonymity of donors is guaranteed. Slides should be mailed to:

David M. Dennis
General Biology Section
The Ohio State University
1060 Carmack Road
Columbus, Ohio 43210, U.S.A. ●

SPONSORSHIP OF NON-U.S. MEMBERS

SSAR is expanding its sponsorship of non-U.S. members by requesting contributions to a fund established to defray the membership dues of herpetologists in countries that face difficulties with exchange of foreign currency. We encourage your participation in this program. Please contact our Treasurer, Dr. Henri C. Seibert, if you can assist in the identification of colleagues who can benefit from this program. All contributions are tax deductible. ●

ZOO LIAISON COMMITTEE REPORT

The SSAR Zoo Liaison Committee has established a liaison with the Species Survival Plan (SSP) group of the American Association of Zoological Parks and Aquariums (AAZPA). The intent of this is to inform the SSAR membership of the conservation-oriented activities of zoo-based members, and to perhaps involve other SSAR members in the SSP programs. AAZPA Conservation Coordinator Thomas J. Foose provides this summary of SSP herp activities to date:

The AAZPA Species Survival Plan is an attempt to develop more scientific and coordinated programs to propagate endangered and unique taxa in captivity. It should be emphasized that the primary objective of such captive propagation is to reinforce, not replace, natural populations by assisting in the preservation of species gene pools.

Gene pool preservation requires that captive collections be managed as biological populations, hence the need for collective and coordinated activity. Moreover, the limited capacity of captive facilities and resources in relation to the number of taxa in need of help (potentially thousands) and the size of the populations necessary for long-term viability (at least hundreds of individuals) require that allocation of the captive habitat also occur in a collective and coordinated way. Thus the SSP attempts to confront two major problems:

(1) designation of the taxa for the program;
(2) management of the designated taxa as biological populations to preserve gene pools.

To date, one amphibian taxon (the Puerto Rican crested toad, *Bufo lemur*) and three reptile taxa (Chinese alligator, *Alligator sinensis;* Dumeril's ground boa, *Acrantophis Dumerili;* Aruba Island rattlesnake, *Crotalus unicolor*) have been designated for the SSP. Many more are anticipated, but the early strategy has been to develop programs that can serve as models. Once they are organized and operating well, the SSP can be extended to many more taxa. Indeed what is needed in the near future is a comprehensive and systematic analysis of all the major herp radiations (e.g. turtles, crocodilians) to assign priorities for the captive habitat available. Bill Zeigler of Metrozoo-Miami has already initiated this process for crocodilians. Even further, Hugh Quinn of the Houston Zoo has commenced formulation of a masterlist of herps for SSP treatment.

Each SSP program is organized around a leader known as the Species Coordinator. Since population analysis and management necessitates good records, each program also needs a Studbook Keeper, who often is the same person as the Species Coordinator. Species Coordinators and Studbook Keepers appointed so far for SSP taxa are:

Taxon	Species Coordinator	Studbook Keeper
Bufo lemur	Rick Paine, Buffalo Zoo	
Alligator sinensis	John Behler, New York Zoo. Soc.	
Acrantophis dumerili	John McLain, Houston Zoo	Rick Hudson, Ft. Worth Zoo
Crotalus unicolor	Andrew Odum, Houston Zoo	Karl Peterson, Houston Zoo

Assisting the Species Coordinator and Studbook Keeper is a Propagation Group of 9 persons elected from and by all the participating institutions in a program. Institutions document their involvement in a program by signing a Memorandum of Participation.

The core of an SSP Program is the Masterplan that provides recommendations for genetic and demographic management, i.e., mate selection, breeding schedules, animal relocations, and culling programs. The objective is to provide a genetically diverse and demographically stable population. Masterplans have already been formulated for the toad and the rattlesnake.

Since support of natural populations is the ultimate goal of SSP programs, reintroduction projects are of particular interest and importance. The Puerto Rican crested toad program has already reintroduced captive hatched toads into the natural range.

More details about each SSP program can be obtained from the Species Coordinators, Studbook Keepers, Hugh Quinn, and Bill Zeigler. The Aruba Island rattlesnake program is also publishing a newsletter which is available from Andrew Odum.

CAREERS IN HERPETOLOGY

The Society has recently published "Herpetology as a Career," which describes opportunities and academic preparation for a career in herpetology. The brochure is intended for students, counselors and others who have a strong interest in amphibians and reptiles.

Single copies are available free from the Publications Secretary; additional copies may be purchased for 25¢ each. SSAR members are encouraged to provide a copy of this brochure to those individuals in their communities who are frequently asked about such matters. ●

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1986 Grants-in-Herpetology Program. This Program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. All applicants (or their advisor or sponsor) must be a member of SSAR. Grant proposals will be considered in the following areas.

1. GRADUATE STUDENT HERPETOLOGICAL RESEARCH. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.
2. HERPETOLOGY-ORIENTED CONSERVATION. Proposals should address research on endangered or threatened species at the state, national or international levels, or address research on critical herpetological habitats. Proposals may be received from individuals only.
3. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.
4. HERPETOLOGICAL RESEARCH IN ZOOS. Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.
5. FIELD WORK (Auto mileage). Proposals may address any area of herpetological research and may be submitted by any member of SSAR. Funding will only be granted for expenses associated with auto travel for collecting (or observing) study animals.

Each proposal must include the following information: A) *Abstract,* B) *Background & Objectives* of the proposed project, in terms of its relevance to herpetology, C) *Methods* of carrying out the research or conducting the project, D) *Budget* for the project, which should not exceed $430 in each category, and E) *Curriculum Vitae* and *Letter of Support* (if applicable). The proposal must be typed double spaced and must *not* exceed five pages, excluding cover page, abstract, budget, curriculum vitae, and bibliography.

Successful applicants will be expected to submit to SSAR a written report of their research or project within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to *The Journal of Herpetology* or *Herpetological Review.*

Individuals submitting proposals must designate to which of the five areas their proposals applies. All proposals must be typewritten, submitted in duplicate, and postmarked no later than **31 JANUARY 1986.** Failure to meet the deadline or follow the guidelines may result in rejection of the proposal. The awards will be announced by 15 March 1986. Submit proposals to:

Thomas H. Fritts
U.S. Fish & Wildlife Service
Department of Biology
University of New Mexico
Albuquerque, New Mexico 87131, U.S.A.

If you are employed by an organization which will match donations made to non-profit educational organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology program. ●

ABSTRACTS OF 1985 GRANTS-IN-HERPETOLOGY WINNERS

The SSAR Grants-In-Herpetology Committee receives, evaluates and prioritizes grant proposals from members in good standing in the SSAR. The Committee awards small grants (up to roughly $450) to the best proposal in five categories. In order to stimulate additional interest in these grants, we are publishing the abstracts of the winning proposals for 1985.

CONSERVATION RESEARCH

Lee A. Fitzgerald, Department of Biology, Museum of Southwestern Biology. "Reproductive Biology and Demography of *Caiman yacare* and *Caiman latirostris* in Paraguay."

Two endangered species of caimans occur in Paraguay: *Caiman latirostris* and *Caiman yacare.* Many local populations of both species have been exterminated by hide hunters without regard to either the species or the hide industry that is based on their harvest. I propose an eight month study that will quantify parameters of breeding biology and demography of both species in National Park Tinfunque in the Paraguayan Chaco. This research will help answer questions relevant to herpetology and conservation such as: Which environmental factors influence *Caiman* breeding cycles? How do the two species use the habitats available to them? What are the differences and similarities in the reproductive biology and population dynamics between the two species? Which factors limit reproductive success? What steps should be taken to promote the recovery of these species? The ultimate goal of this study is to provide scientifically defensible recommendations for conservation efforts for caiman in Paraguay. The completion of demographic and reproductive studies and the training of Paraguayan biologists and technicians are our immediate goals. These goals will be accomplished by quantifying breeding and demographic parameters such as clutch size, principal sources of mortality, reproductive success, and population size and age structure. The results of the study will be used to formulate recommendations for a management plan for caimans in Paraguay. The study will be conducted in collaboration with the Paraguayan National Forest Service, National Biological Inventory Project. Counterpart training will be conducted in all aspects of the study.

GRADUATE STUDENT RESEARCH

1. Frances J. Irish, Harvard University. "The Evolution of Tooth Replacement Patterns in Snakes: Mechanisms and Implications."

The primitive pattern of tooth replacement in squamate reptiles is approximately alternate - every other tooth is firmly attached to the jaw (ankylosed) while the intervening visible teeth are loose. Colubrid snakes exhibit a number of derived replacement patterns; in the most extreme case, all teeth are shed and replaced simultaneously. Examination of preserved specimens of 194 colubrid genera has generated the following hypotheses:

a. Observed deviations from the primitive alternate replacement pattern are produced by heterochrony (changes in the relative timing of replacement events).

b. Simultaneous replacement has evolved separately in three of the currently recognized colubrid subfamilies; in all of these species, active tooth replacement occurs only during epidermal sloughing. This suggests that tooth replacement is coupled to the epidermal sloughing cycle in all snakes.

c. Simultaneous replacement is correlated with a diet restricted to earthworms and/or molluscs.

The first two hypotheses cannot be critically tested without the development of a marking technique which allows individual tooth generations to be followed through time. I propose to develop such a technique using fluorescent dyes (tetracycline and alizarin in red S, which have been used successfully to label calcified tissues in vivo in mammals), and apply it in a year-long study of the tooth replacement and epidermal sloughing cycles of juvenile *Thamnophis sirtalis* (a locally common species with alternate tooth replacement).

2. George R. Cline, Oklahoma State University. "Gene Flow Between Two Forms of the Gray Treefrog, *Hyla chrysoscelis* in Geographic Areas of Contact."

Hyla chrysoscelis and *Hyla versicolor* are members of a cryptic diploid-tetraploid species pair in North America. The two species are distinguished by karyology and by subtle differences in their calls. Two forms of the diploid, *H. chrysoscelis* are recognized: western populations have shorter calls and are fixed for a slow electromorph of lactate dehydrogenase (LDH), while eastern populations have longer calls and are fixed for a fast electromorph of LDG. Clinical variations might explain the observed differences between the two forms, but previous studies have been hampered by separation of the diploid range by the tetraploid. I will sample *H. Chrysoscelis* in Oklahoma, Kansas, Missouri, and Arkansas where the eastern and western forms are not separated by the tetraploid species and are thus potentially free to hybridize. Acoustics of the calls will be analyzed on a sound spectrograph. Ploidy levels will be verified by measurement of blood cell size. Thirteen morphological characters will be submitted to multivariate analysis. Tissue samples will be processed electrophoretically

to determine genetic composition of the populations. These three methods have never been simultaneously applied to members of this complex in areas of sympatry of the two diploid forms. Maintenance of genetic and acoustical identities would provide evidence supporting the hypothesis that two diploid species exist in this group. Pilot studies now underway verify differences between forms of *H. chrysoscelis* that have previously been reported in the literature and are helping narrow the search for the geographic zone of contact between the eastern and western forms.

REGIONAL SOCIETY RESEARCH

Harold F. De Lisle, The Southwestern Herpetologists Society. "The Present Status of the Herpetofauna of the Santa Monica Mountains."

This proposal is designed to study the reptile and amphibian species and populations in the Santa Monica Mountains, Los Angeles County, California, as compared to those of the 1950s and 1960s when extensive collecting was last done in this area by the Los Angeles Co. Museum of Natural History, the University of California, and several members of the Southwestern Herpetologists Society. An attempt will be made to determine the effects of urban development on the herpetofauna of this region for which major land use decisions are now being made by the U.S. Park Service, California State Division of Parks and Recreation, and several local and private agencies.

FIELD WORK

1. Douglas E. Ruby, Department of Biological Sciences, Drexel University. "Variation in Territorial Behavior in the Iguanid Lizard, *Sceloporus iarrovi.*"

Different behavioral "strategies" should be selected in populations which offer distinct sets of opportunities for acquiring resources (such as food and mates) (Dunbar 1982; Dominey 1984 and others). The factors that affect this behavioral flexibility are less well understood in amphibians and reptiles compared to other groups of vertebrates. I propose to investigate apparent non-territorial behavior in a dense population of the iguanid lizard *Sceloporus iarrovi* located on Mt. Graham in southeastern Arizona simultaneously with another high elevation population in comparison with published work on typical behavioral patterns. By simultaneously documenting time budgets, food levels and feeding rates, and male access to females of these two populations, differences in behavior can be related to variation in resource levels and spacing patterns. The data collected will permit testing of hypotheses about the value of territorial behavior for controlling resources (food, mates, basking sites, etc.) given different densities and levels of resource availability. This information will contribute toward elucidating the relationship between the social and mating structure of a population and the ecological conditions (density, feeding levels, demography, climatic conditions) bearing upon a population.

2. Chris T. McAllister, Renal-Metabolic Lab, Veterans Administration Medical Center. "The Role of Environmental Constancy on Oxygen Consumption and Thermal Sensitivity in Relict Populations of Hemidactyline Plethodontid Salamanders."

Cave and spring ecosystems are fragile and energy-limited natural resources. They are important components of the subterranean hydrology in many areas, especially those with limestone or dolomite formations. Caves and springs are inhabited by endemic biota which frequently are rare, endangered or otherwise threatened. The inherent fragility of these ecosystems renders them susceptible to human intrusions. Potentially harmful activities range from cave visitation and exploration to water pollution. Recent interest in utilizing underground water in residential and commercial heat-exchangers portends to be a thermal threat to aquatic biota which have evolved under thermal constancy (e.g., subterranean water has relatively constant temperature annually, lower than surface temperatures during the summer and higher in the winter). The proposed investigation examines thermal sensitivity, adaptations and physiological ecology of an obligate cave salamander *(Typhlomolge rathbuni)* and two spring salamanders *(Eurycea nana* and *E. neotenes).* The results will be compared with the extensive literature on metabolism and thermal acclimation of salamanders from variable thermal environments.

ZOO RESEARCH

Victoria A. Teubner, University of Toledo. "Endocrine and Behavioral Aspects of Reproduction in the Haitian Boa *(Epicrates striatus)."*

Many of the world's reptile species are classified either as threatened or endangered. Attempts to augment populations by captive breeding programs have been largely unsuccessful. Once many reptiles are removed from their natural habitats and placed in captivity, their reproductive rates decline drastically, primarily because of our failure to recognize and provide the proximate cues found within the natural environment which induce reproduction. These cues fall into the categories of external environmental factors (temperature, photoperiod, moisture, food quality) and social stimulation (reproductive behavior and presence or absence of other conspecifics). These two major factors in turn affect internal regulation systems (i.e., production and secretion of the reproductive hormones). In this study, males from a tropical snake species, the Haitian Boa *(Epicrates striatus)* will be maintained under optimal conditions during the first year in order to define the breeding season and to insure a population of breeding animals. The boas will then be subjected to a variety of experimental environments which will determine the importance of temperature, photoperiod, moisture, and the presence of females upon their reproductive cycle. Male reproductive status will be assessed by behavioral observation and monitoring of serum testosterone levels by radioimmunoassay. Testosterone will be characterized using high pressure liquid chromatography.

NEW SUBSCRIPTION CATEGORY — *HERP REVIEW* ONLY

At SSAR's 1985 Annual Meeting, the Society approved the addition of a separate subscription to *Herpetological Review.* Recognizing that some members of the herpetological community may not find subscription to all of our publications equally useful, the SSAR Board established this category at a cost of $10 per year. Individuals selecting this option will not be members of the Society nor will they receive the Journal of Herpetology or other publications offered with membership. However, subscribers are encouraged to register for and attend our annual meetings and may join the Society as regular members at any time.

A subsciption form will appear in the next issue of *HR* and as part of the dues envelope which will be distributed in September. Please mention this new category to friends and colleagues whom you think will benefit from it.

HENRI SEIBERT,
SSAR Treasurer ●

LETTERS TO THE EDITOR

ICZN PETITIONS

Cyrtodactylus pelagicus; Correct Usage

EDITOR:

In a recent study of gecko relationships, Kluge (1983. Copeia 1983 (2):465-475) discovered that the Pacific naked-toed gecko *(Cyrtodactylus pelagicus)* and several other Indoaustralian species represented a unique lineage. He assigned this monophyletic lineage of species to a new genus *Nactus.* In the same article, he also stated that the holotype of *Gymnodactylus arnouxii* A. Duméril, 1851, and *Heteronota pelagica* Girard, 1857, were identical and, thus, *arnouxii* is the senior synonym.

Kluge proposed, incorrectly, that the commonly used name *pelagica* be replaced by the unused *arnouxii.* The International Code of Zoological Nomenclature (Article 23 in both the 1961 and 1985 editions) states that should the application of the Principle of Priority upset stability of use or cause confusion in use, existing use should be maintained and the case be referred to the Commission. Since Kluge ignored this nomenclatural dictum, I have applied to the Commission for the suppression of *arnouxii* and the placement of *pelagica* on the Official List of Specific Names.

I wish to notify zoologists working in the Pacific that *Nactus pelagicus* (or *Crytodactylus pelagicus*) is the correct name and should be used until the Commission rules otherwise.

Conservation of the Name *Anniella pulchra* for the California Legless Lizard

EDITOR:

Hunt (Copeia 1983:79-89) recently rearranged the nomenclature of the two species in the legless lizard genus *Anniella*. He placed *A. geronimensis* Shaw, 1940 in synonymy with *A. pulchra* Gray, 1852 and applied this name to the southernmost species. In doing so, *A. nigra* Fischer, 1885, replaced the name *pulchra* for the northernmost species, and the southern subspecies of *nigra* became nameless, which was redescribed as *A. n. argentea* Hunt, 1983. In proposing this rearrangement, Hunt overturned a nomenclature which had been stable for over 130 years.

If the name *pulchra* as it applies to northernmost species of *Anniella* was rather obscure, receiving little attention from research and popular writing, the changes would have been relatively inconsequential, or at least innocuous. However, we found over 200 usages of the name *pulchra* referring to the northernmost species, including many significant morphological contributions, and of equal importance, popular field guides and state check lists; and our list is doubtless incomplete. (Our literature list will be sent upon request to RWM.) Hunt's changes are particularly unfortunate because the nomenclature rearrangement was unnecessary, and thus unwarranted.

The origin of the problem stems from Gray [1852, Ann. Mag. Nat. Hist. (2)10:437-440] not designating a specific animal as the holotype of *pulchra* in his original description. Richardson [1854, Reptiles and Fish, Part 3 *In:* E. Forbes (ed.), Zoology of the Voyage of the H.M.S. Herald . . .] redescribed and figured "Gray's holotype." Boulenger [1885, Catalogue of the Lizards in the British Museum (Natural History)] reported that the single specimen donated by Gray in 1852 via Richardson to the British Museum (Natural History) was the holotype of *pulchra*. Hunt (1983) discovered that the supposed holotype of *pulchra* neither matched the description of Richardson (1854) nor could be identified as the specimen originally described by Gray (1852). Indeed, Hunt (1983:80) stated "in a strict sense the name *pulchra* may be a nomen dubium since it is not possible to verify absolutely the specimen or species on which Gray based his ('cursory') description . . . ." Nevertheless, Hunt "hypothesized" that Richardson described and figured the wrong specimen of two - a specimen belonging to a species other than that described by Gray. An agonizing question about the true identity of the holotype thus remains.

Because of the necessity of a hypothesis to account for the discrepancy in the identity of the holotype, Hunt's nomenclatural rearrangement is only an educated, yet conjectured, opinion, and as such is not binding; his nomenclature does not have to be followed. Nevertheless, because the name *pulchra* has been extensively applied in the literature to the northernmost species of *Anniella*, we believe it desirable to set aside the "holotype" referred to by Boulenger (1885) and designate in its place a neotype thereby stabilizing the nomenclature. Before preparing a petition to the International Commission of Zoological Nomenclature (ICZN) for use of plenary powers to accomplish this goal, we sought, and received, the opinions of 15 eminent herpetologists directly concerned with *Anniella* relative to our intentions; the response was overwhelming approval.

Not only is the nomenclatural rearrangement suggested by Hunt based upon an arbitrary decision from ambiguous data, but more importantly it violates the very heart of international nomenclatural regulation to which zoologists preponderantly subscribe as the only safeguard against chaotic anarchy. The objects of the International Code of Zoological Nomenclature include, most importantly, promotion of nomenclatural stability (1985 edition, p. 3). Stability is achieved most commonly by application of the law of priority, but it is expected that when such application threatens instead of promotes stability, the case should be appealed to the International Commission of Zoological Nomenclature. The Commission is empowered to suspend application of any part of the Code in order to preserve stability (Art. 79), and it is the obligation of any taxonomist to avail himself of the Commission's plenary powers in any significant threat to nomenclatural stability.

We, and obviously most of our canvassed colleagues, regard the proposed nomenclatural rearrangement in *Anniella* as a significant and unnecessary threat to nomenclatural stability, hence worthy of a petition, now submitted, for consideration of the case by the Commission. Article 80 of the Code requests that "existing usage" be maintained until a decision by the Commission is published. "Existing usage" is defined as "the most common usage," certainly in this case, that of the century, and more, prior to 1983.

This advance notice of our petition which has been submitted to the ICZN is provided at the suggestion of Dr. C. Gans (University of Michigan) in an attempt to minimize further confusion in the literature. We strongly urge authors and editors to observe the regulations of the Code, and not to follow Hunt's proposed nomenclature, at least until the outcome of our petition is known. Use of his names can only result in greater confusion than already anticipated, especially in literature indexing services. On the other hand, a delay in the use of Hunt's nomenclature will not add to confusion, especially if authors specify the use of *pulchra* sensu Richardson (1854).

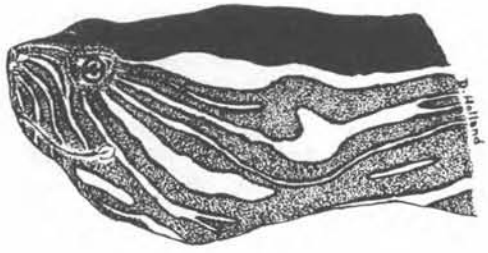
EDITOR:

An investigation of turtle breeding farms in Louisiana by Clifford Warwick, wildlife consultant to BBC's TV program, *Wildtrack*, as published in *BBC Wildlife*, September 1984, has been brought to the attention of The Humane Society of the United States.



The article reveals that turtle farmers in the United States are exporting 4 to 5 million hatchlings annually for the pet trade and that the farmers may be taking up to 100,000 adult red-eared turtles (*Pseudemys scripta elegans*) from the wild each year to replace that part of their breeding stock which has died during the winter. It is stated that there are about 25 farms in Louisiana and another 25 in other southern states. The four farms visited in Louisiana averaged 27,000 breeding adults each in artificial ponds (about 13,000 to a pond). These four farms collected a total of 9,400 adults from the wild each year. The farmers admitted to a noticeable depletion of local stocks, and it was learned from the author, although not mentioned in the article, that some farmers are buying wild-caught adults from a dealer in Arkansas.

The article states that farmers are making efforts to get the existing domestic ban by the Food and Drug Administration on the sale of hatchlings lifted, which, if they are successful in so doing, would provide a market for an additional 10 to 15 million hatchlings, and would seem to necessitate the taking of three times as many adults from the wild and would possibly lead to the starting up of some 50 farms that closed after the ban was issued.

The Humane Society of the United States generally opposes the keeping of wild animal species by the general public and the trade in such species. In this particular case, the HSUS is concerned over the drain on wild turtle populations in addition to its concern over the health hazard to non-U.S. children and the fate of the turtles, the vast majority of which will die in the first six months due to improper care and abuse in homes. The HSUS would like to see the present export trade in turtle hatchlings stopped.

Feeling that the membership of the Society for the Study of Amphibians and Reptiles shares these concerns, we thought it advisable to make known to your organization the above information.

NOMENCLATURE OF THE AUSTRALIAN HERPETOFAUNA: ANARCHY RULES O.K.

EDITOR:

At some stage in their careers most herpetologists encounter a situation in which a planned action is in some way constrained, following a last-minute examination of the Code for Zoological Nomenclature. Whether the experience induces a sense of awe, disagreement, disappointment, or plain frustration, is less significant than the fact that it involves conceding that the directives of the Code are highly influential, if not always respected.

In general, Australian herpetologists have acted more conservatively over the years (in a taxonomic sense) than the common view of their national image might lead one to anticipate. Whether this inclination simply is due to the lack of access to literary dynamite, or to an inherent reluctance to use such explosives is questionable. Certainly it can be argued that national deficiencies in library resources (particularly of significant 18th and 19th century publications), places Australian herpetologists at a huge disadvantage if they desire to participate in the most masterly of all taxonomic sports: The Discovery of Primary Homonyms.

In recent years the nomenclature of many Australian taxa has become unstable, reflecting the increased level of interest in systematics and, particularly, the rising number of contributors. Insofar as the Australian Amphibia are concerned, the current areas of disagreement are at four levels. Firstly the use of the family names Pelodryadidae and Myobatrachidae for the Hylidae and Leptodactylidae respectively; secondly the recognition of genera such as *Philoria, Metacrinia* and *Paracrinia* (perhaps a splitting or lumping issue); thirdly the use of particular species names such as *Litoria serrata* or *L. eucnemis* for the Australian population of this species and, fourthly the correct specific suffices for several species of *Cyclorana.*

One would anticipate that the current state of flux is a transient situation, and that a stable nomenclature will emerge shortly. But this expectation is unlikely because an entirely new dimension has been added in the form of contributions by Wells and Wellington (1984, 1985) in a journal that they apparently control: "The Australian Journal of Herpetology."

The first attempt to compile a list of the entire herpetofauna of Australia was that of Cogger, Cameron and Cogger (1983). Within just a few months of its publication Wells and Wellington (1984) produced a reptile checklist involving "a few re-interpretations of our own." This description of their work is far too modest because the 57 pages include more taxonomic changes than had been proposed by all other authors in the previous decade.

The response of contributors from the Australian Society of Herpetologists representing the professional field, was one of condemnation (*Herp. Review* 16(1):1985). This action had no effect, and there has now emerged from the same stable "Aust. J. Herp. Suppl. Ser. No. 1," a 98 page treatise entitled, "A Classification of the Amphibia and Reptilia of Australia." Eight pages of this work are devoted to the amphibia. With a remarkable economy, included in those pages are the resurrection of 12 genera, the description of 19 new genera, the resurrection of 33 species, and the description of two new species. So in just eight pages the number of genera of Australian frogs has been increased by 150%, and the number of species by 20%.

Does it matter one jot what Wells and Wellington perceive? My first inclination is to assert that it doesn't. They are entitled to express opinions far removed from those of other workers if that is their desire. But if nomenclature is to remain a dynamic process, it matters a great deal if we follow the assumption that adopted systematics is in some way beholden to the most recent published contribution.

I've always regarded the current nomenclature of taxa to be valid (and so supported by me) until argued otherwise. Hence to effect change in the *status quo* involves the healthy exercise of arguing a case, producing data in support of the contrary stand, and running the gauntlet of the scientific community via the refereeing process. It may not be an infallible procedure, but at least it ensures that nomenclatural changes are not effected solely following a whim on the part of a contributor. It has the effect that we may not agree with the results, but at least we can object to them via a similar avenue.

It follows that I do not support the actions of Cogger et al. (1983) involving introducing nomenclatural changes in a checklist, simply because it provided no explanation of the reasons or justifications for the changes. But Cogger et al. (1983) are true-blue conservatives when their nomenclatural changes are compared with those of Wells and Wellington (1985).

Take, for example, the conclusions of Wells and Wellington (1985) relating to the small frog *Ranidella signifera.* In the space of just 16 lines they resurrect *Ranidella englishi, R. halmaturina, R. montana* and *R. varius* from the synonymy of *R. signifera.* The most detailed account explaining any of these actions is for *R. halmaturina* which reads, "Herein formally resurrected from the synonymy of *R. signifera; R. halmaturina* is believed confined to Kangaroo Is., South Australia." It happens that these conclusions are at variance with the evidence published (Littlejohn 1959). Even if Wells and Wellington have a hot-line with the Deity, the above conclusion is nonsense. Few Australian frogs have been studied in a detail comparable to that of *R. signifera.*

Because of the divergence between most of the taxonomic and nomenclatural decisions of Wells and Wellington (1985) with data published, two options are open to those persons who disagree with these authors. One is to refute each of their decisions *seriatim;* but such an action would constitute an admission that their publications are legitimate expressions of scientific opinions. The Code may well demonstrate that Wells and Wellington have fulfilled the various criteria of publication, but the Code assumes (quite wrongly) that all zoologists will respect its Recommendations. The privately published journal in which an author controls the acceptance of papers is a back-door exercise. I believe it is time that this avenue of effecting nomenclatural changes be blocked.

The second option open to herpetologists in Australia is to ignore the Wells and Wellington publications in their entirety. The action will be at variance with the intent of the Code, but I submit that if the Code really is oriented to maintaining stability and universality of nomenclature, the Commission should be concerned at the action of Wells and Wellington — steps that undermine the total framework. And if it is concerned and either unwilling or unable to act, it can scarcely criticise my proposal.

NEWSNOTES

INDEX TO THE GENERA OF AMPHIBIA: A DEVICE TO ASSIST CURATORS

A limited number of copies of the 4th edition are available at cost. This index is privately produced and has 41 pages (8½ x 11 inches) plus stiff paper covers. It was initially distributed at the ASIH/HL/SSAR meeting in the summer of 1984. Included are all available generic names within the living families of amphibians. Each name is followed by its author(s), year, and in the case of synonyms the currently accepted valid name. The index has two parts, a straight alphabetical list followed by the same names grouped by families.

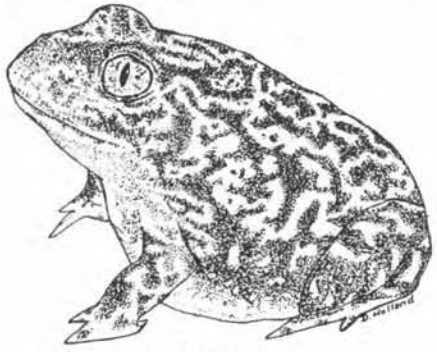
For each copy please send $2 plus $1 for handling to:

John S. Applegarth
Box 532 - Lorane Route
Cottage Grove, Oregon 97424, U.S.A. ●

WILDLIFE REHABILITATION GRANTS

The Awards and Grants Committee of the National Wildlife Rehabilitation Association would like to announce its small grants program. Funding is available to support a single $1000.00 project or several smaller projects that add up to $1000.00 for a project in the field of wildlife rehabilitation.

Applicants must demonstrate financial need, and submit a typewritten proposal which includes name(s) and résumé of personnel involved, objectives, a brief statement of literature reviewed, methods, and an itemized budget. An annual progress report will be required.



Two additional awards are:

Lifetime Achievement Award - This would go to an individual whose primary identification is that of a wildlife rehabilitator who has contributed to the field in a major way for many years. The awardee will receive a plaque, $100.00 and free conference registration. The award will be presented at the N.W.R.A. conference.

Significant Achievement Award - This would go to a person who has contributed something of significant merit to the field of wildlife rehabilitation within the last 2 years. Contribution can be a research finding, publication, organization of a program, etc., as long as the major theme is that of wildlife rehabilitation. The awardee would receive the same benefits as for the Lifetime Achievement Award.

Deadline for the submission of proposals and award nominees is 1 December 1985. Nominations and proposals should be submitted to:

Dr. Daniel R. Ludwig
Willowbrook Wildlife Haven
Forest Preserve District of
DuPage County
P.O. Box 2339
Glen Ellyn, Illinois 60138, U.S.A.

JOB OPENING

The Smithsonian Tropical Research Institute in Panama is seeking to fill the position of Manager in the Iguana Management Project. This is a tentative two-year position, beginning 15 February 1986. Minimum requirement: Master's degree in zoology. Candidates must be fluent in Spanish and English, have an interest in reptiles, and be able to work well with Latin Americans. Organizational duties include administration, field work, supervision of experiments and B.S. degree students, and interfacing between Project and Panamanian institutions and individuals.

Salary: $12,000 and up, depending on qualifications. The first three months of employment will represent a probationary period. The position is renewable after one year.

Send a Curriculum Vitae and three letters of recommendation to:

Dagmar Werner
Smithsonian Tropical Research Institute
APO Miami, 34002, U.S.A. ●

LEGISLATIVE ALERT

FEDERAL REGISTER NOTICES

Volume 49, No. 244, p. 418. 18 December 1984. 50 CFR Part 17. Notice of petition findings and review. Relevant information or comments can be submitted until further notice.

This notice announces that four petitions to add five species to the list of endangered and threatened wildlife may be warranted and announces the review of the status of three of the species. Petition for **Coeur d'Alene salamander** *(Plethodon vandykei idahoensis)* was submitted by Mr. Thomas Koenigs on 5 July 1984, received by USFWS on 17 July 1984. Recent declines in populations may be attributed to human disturbance. Petition is for endangered status.

Petition for **gopher tortoise** *(Gopherus polyphemus)* was submitted by Drs. Ren Lohoefener and Lynne Lohmeier on 15 July 1984. Petition is for endangered status for that population occurring west of the Tombigbee River in Alabama, Louisiana, and Mississippi. Recent declines can be attributed to habitat destruction and killing by humans.

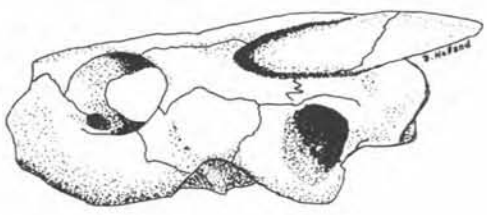
Submit comments to Associate Director—Federal Assistance (OES), U.S. Fish and Wildlife Service, Washington, D.C. 20240.

Volume 50, No. 26, pp 5279-5282. 7 February 1985. 50 CFR Part 23. Notice of proposed amendments. Foreign proposals to the Convention on International Trade in Endangered Species of Wild Flora and Fauna. Comments were accepted until 15 March 1985.

The CITES regulates international shipment of certain wildlife and plant species. This notice announced proposals submitted by certain foreign countries and requested comments from the public to help formulate U.S. policy statements. Proposals will be reviewed during the April and May 1985 meeting of the convention.

The petition included the following species: **Nile crocodile** *(Crocodylus niloticus)*, **saltwater crocodile** *(Crocodylus porosus)*, **green sea turtle** *(Chelonia mydas)*, **hawksbill sea turtle** *(Eretmochelys imbricata)*, **Indian sawback turtle** *(Kachuga tecta tecta)*, **Indian flap-shelled tortoise** *(Lissemys punctata punctata)*, **Indian softshell turtle** *(Trionyx gangeticus)*, **peacock softshell turtle** *(Trionyx hurum)*, **broadheaded snake** *(Hoplocephalus bungaroides)*, **Bengal monitor** *(Varanus bengalensis)*, **yellow monitor** *(Varanus flavescens)*, **Monteverde toad** *(Bufo penglenes)*, **Asian bullfrog** *(Rana hexadactyla)*, **Indian bullfrog** *(Rana tigerina)*, and **platypus frog** *(Rheobatrachus* spp.). The reader is referred to the federal register and other sources to determine further details of the petitions and the U.S.' proposed positions.

Volume 50, No. 40, pp. 8122-8131. 50 CFR Parts 450-453. Final Rules Applying for Endangered Species Act Exemptions and for Endangered Species Committee Considerations of Such Applications. Effective date was 1 April 1985.



This rule implements the changes in the exemption process made by the Endangered Species Act. The rule covers the process from the time of application to the final determination by the committee. Exemptions are from section 7, which requires federal agencies to comply with the intent of the Act. This notice summarizes the background and rule-making actions of the USFWS in this issue.

Volume 50, No. 63, pp. 13054-13055. 50 CFR Part 17. Notice of petition findings and review . . . for two herptiles. Comments may be submitted until further notice.

The service announces findings that a petition to reclassify the **American alligator** *(Alligator mississippiensis)* to threatened s/a throughout South Carolina has presented substantive data to warrant review of the action. A petition to list the **desert tortoise** *(Gopherus agassizii)* also warrants further review. Also announced is a review of the status of the **alligator** in South Carolina. The petition to reclassify the alligator was submitted by the South Carolina Wildlife and Marine Resources Department on 27 July 1984. The petition to list the gopher tortoise as endangered was submitted by the Defenders of Wildlife, The Natural Resources Defense Fund and the Environmental Defense Fund on 11 September 1984. The petition is to list the entire population of the species; currently only the Beaver Dam Slope, Utah population is listed as endangered.

OTHER GOOD NEWS: The Endangered Species Technical Bulletin (Volume IX, No. 11, 1984, pp. 3, 11) tells us that a 327 acre area of beach at Sandy Point on the island of St. Croix, USVI, was purchased in September 1984 for protection as a national wildlife refuge. Of particular note is that this area is one of the most important nesting areas for the critically endangered **leatherback sea turtle** *(Dermochelys coriacea)*, as well as for the endangered **hawksbill** *(Eretmochelys imbricata)* and the threatened **green sea turtle** *(Chelonia mydas)*. This area was previously zoned for commercial development that would have severely impacted the breeding of these species. The cost of the acquisition was $2.5 million, which was appropriated by Congress from the Land and Water Conservation Fund.

SOCIETIES

NEW HERP SOCIETIES

The SSAR Regional Herpetological Society Liaison Committee has recently learned of the establishment of four new herpetological societies. These are:

Kaw Valley Herpetological Society
Rt. 1, Box 29B
Eudora, Kansas 66025, U.S.A.

Lubbock Turtle and Tortoise Society
c/o Dr. Carl Anderson
3311-24th Street
Lubbock, Texas 79410, U.S.A.

South Texas Amphibian and Reptile Society
c/o Greg Luther
P.O. Box 233
Angleton, Texas 77515, U.S.A.

Southern Mississippi Herpetological Society
c/o Ted Crawford
404 Ridge Drive
Biloxi, Mississippi 39532, U.S.A.

Other regional societies are asked to place these new organizations on their newsletter mailing list as exchange members. ●

LUBBOCK TURTLE AND TORTOISE SOCIETY

We are announcing the formation of the Lubbock Turtle and Tortoise Society. The society is an educational and service organization committed to 1) conservation and preservation of turtles in the natural habitat, 2) captive care, and 3) captive reproduction. Members will be assisted in the acquisition of captive specimens.

The society will meet on the 3rd Tuesday of each month at 7 P.M. We currently meet in the home of Dr. Carl Anderson, 3311-24th St., Lubbock, Texas 79410. We will remain there until numbers force a move to larger quarters. For information concerning membership or meetings call (806) 795-9700 evenings and weekends. ●

MEETINGS

ASIH SYMPOSIUM

A symposium on "Snake Behavior and Ecology" will be conducted during the annual meeting of the American Society of Ichthyologists and Herpetologists which will be held on June 15-21 of 1986 at The University of Victoria, Victoria, British Columbia. A number of speakers will review and discuss new research in the areas of snake:

I. Social Behavior and Reproduction
II. Feeding Behavior and Ecology
III. Physiological Ethoecology
IV. Population Ecology

We feel this is a timely symposium and hope all researchers interested in snake ecology and behavior will make plans to attend. For further information concerning this symposium contact:

Neil B. Ford
Department of Biology
University of Texas at Tyler
Tyler, Texas 75701, U.S.A.

Inquiries about the 1986 ASIH meeting should be directed to:

RAIN WATER DRINKING BY THE MANGROVE WATER SNAKE, *Nerodia fasciata compressicauda*

Reptiles may satisfy their water requirements in ways other than by drinking from natural streams and ponds. Meyer (1966) reported that three species of desert lizards *(Holbrookia, Phrynosoma)* lick dew drops. Bradshaw and Shoemaker (1967) observed that Australian desert lizards *(Amphibolurus)* emerge during thunderstorms, run rapidly about and catch drops of water as they fall. It is not clear, however, if the lizards catch rain drops directly, or drink water dripping from rock outcrops. Before thunderstorms the desert tortoise *(Gopherus agassizi)* excavates depressions to catch water (Medica et al. 1980). Three species of African land tortoises *(Psammobates, Kinixys, Homopus)* have recurved plastrons that act as gutters during rain. These turtles raise their hind ends during rain, causing water to flow to their mouths (Auffenburg 1963). The side-winding viper *(Bitis peringueyi)* flattens itself against the substrate during a falling mist, collecting water on its dorsum. The snake then coils and moves its head along its body, licking the water off its dorsum (Louw 1972). This behavior is adaptive to the frequent occurrence of advective fog in the Namib Desert. The following field observation concerns a snake drinking rain water directly.

On 8 July 1983, 2125 hours at Placido Bayou, Tampa Bay, Florida, a *Nerodia fasciata compressicauda* was observed perched 1.2 meters high in a red mangrove tree *(Rhizophora mangle)* during a heavy rain. The specimen was a red phase female, 730 mm snout-vent length and 380 grams. The anterior half of the body was suspended downward from a branch at an angle of 30 degrees from horizontal. Water ran along the snake's body, trickling off the tip of it's mouth. Drinking was indicated by jaw movements. After 3 minutes, the snake raised itself to an angle 5 degrees below horizontal and rested its chin against a twig, continuing its jaw movements. Some water accumulated between the snake's jaw and the twig. After 15 seconds, the snake resumed its original posture, and after another 20 seconds, ceased jaw movements. Upon capture, palpating the live snake forced 2.2 ml of fluid from the snake's stomach. Water from three other specimens was obtained in a similar manner after rain; however, these snakes were not observed actually drinking.

The drinking response of *N. f. compressicauda* was also observed in the laboratory. Nine snakes were kept in an aquarium (505 x 255 x 305 mm) without food and water. When kept in this manner, the snakes congregated and raised their heads above the floor of the aquarium. After 21 days, water was dripped from a pipet upon the snakes' heads. The snakes responded with jaw movements characteristic of drinking. One snake oriented its head upward and moved toward the dripping water while drinking. Five snakes tilted their heads downward while drinking. Three other snakes also tilted their heads downward, but continued to lower their heads until they were drinking from water pooling on the floor of the aquarium. Two of these three snakes also licked water from the floor of the aquarium.

The behavior of one individual illustrated the magnitude of the drinking response to falling drops of water. While the snake was drinking from a bowl, water was dripped upon the snake's head from a pipet. Instead of continuing to drink from the bowl, the snake raised its head above the bowl and drank the falling drops of water. After the pipet was empty, the snake lowered its head and resumed drinking from the bowl. On every successive trial, the snake preferred to drink falling drops of water rather than drink from the bowl.

These observations contradict Pettus' (1958) suggestion that estuarine snakes satisfy their water requirements exclusively from the water content and oxidation of their prey. Estuarine snakes apparently rely upon frequent rain storms for water acquisition. The drinking behavior elucidates how an estuarine snake can inhabit a saline environment without a salt gland.

A COASTAL HABITAT FOR THE FIJI GROUND FROG AND A FIRST RECORD FROM GAU ISLAND

The ground frog (Ranidae: *Platymantis vitianus*) is the rarer of Fiji's two endemic frog species. In the 130 years since it was described (Duméril 1854) only 120+ specimens can be found in museum collections. It has been recorded from the islands of Viti Levu, Vanua Levu, Taveuni, Ovalau, Beqa and Viwa. Until recently I had found only four animals, two from alongside a stream on Taveuni and two from under logs on Ovalau. Zug (1983) found four specimens on Ovalau at an elevation of at least 200 m. These frogs, all from under rotting vegetation, were more than 100 m away from the nearest permanent stream. This contrasts strongly with the stream habitat reported by Gorham (1968) and Pernetta and Goldman (1976). Gorham listed a Fiji Museum specimen from the island of Viwa, but in his map showed Viwa Island in the Yasawa Group. That dry island chain is unsuitable habitat for frogs and the Fiji Museum specimen probably comes from Viwa Island in the Rewa Delta. Viwa (178° 37' 30"E, 17° 56' 30"S) is a small hilly island approximately 1.5 km by 0.75 km.

The vegetation includes an extensive mangal (*Rhizophora* spp) along the coast and several areas of Ivi *(Inocarpus fagiferus)* forest further inland. The hill vegetation is secondary rainforest heavily disturbed by agriculture, interspersed with many food trees and shrubs. There are no permanent streams on Viwa and very few pools of standing water. The ground frog however lays terrestrial eggs which develop directly into froglets (Gorham 1968). There is a small Fijian village (population 100) on the northern coast.

In November 1982 J. Gibbons collected four Viwa specimens for me, all from under logs. I visited Viwa on 11 March 1983 and captured 8 specimens of *P. vitianus.* One juvenile (SVL 36.8 mm) was captured during the day above leaf litter in Ivi forest at the eastern end of the island. The area was riddled with large land crab *(Cardisoma carnifex)* holes and under tidal influence. The remaining specimens were caught at night on stones or tidal debris at the high tide mark on the beach. One specimen on the beach side vocalised loudly upon capture with a series of croaks. It continued to call until released. This is the first record of vocalisation by *P. vitianus.* Although Viwa villagers recognise the mating call of the cane toad *Bufo marinus,* they have apparently never heard the ground frog.

Visits on 15 April and 19 May yielded 7 and 9 specimens respectively. On 15 April three frogs were captured from the high tide mark, the others from the steeply sloping bank above the beach. On 19 May two specimens were collected from the highly saline Ivi forest leaf litter (see colour photograph, Ryan 1984), three specimens from the high tide mark and four from the bank. No frogs vocalised.

On 11 March I brought a large female (90 mm SVL) back to Suva. During the return trip in an open punt, her plastic bag filled partially with salt water. Despite 40 minutes immersion the frog apparently suffered no ill-effects. Forty-eight hours after capture she produced a fecal pellet which contained the remains of a large crab. These observations suggest that ground frogs actively forage on the beach and are somewhat resistant to salt water.

In December 1983, J. Gibbons collected 2 specimens of *P. vitianus* from Gau. Gibbons (pers. comm.) informed me that the people from the south end of Gau are familiar with *P. vitianus,* which although difficult to find is not necessarily rare on the island. Gau Island (179° 19'E, 18° 1'S) is a mountainous volcanic island 20.9 km by 7.2 km. A female, 75 mm SVL, was captured from under a tree fern log in the rainforest (*ca.* 50 m elevation), the other an immature female, 53 mm SVL, was from a wet dalo (*Colocasia* sp.) plantation (*ca.* 15 m elevation).

All islands from which the ground frog have been reported are high volcanic islands. The species may occur also on Koro and other smaller islands.

This is the first record of *P. vitianus* from Gau. Based on these observations and those by Zug (1983), *P. vitianus* uses a variety of habitats ranging from rainforest floor, streams, stream banks and beaches. These extend considerably its previously known habitats.

ACKNOWLEDGMENTS

I wish to thank the people of Viwa for the great help and hospitality they have extended to me. John Gibbons and Tim Emery accompanied me on field trips and their support has been much appreciated. This work has been funded by a University of the South Pacific research grant (R106) which is gratefully acknowledged.

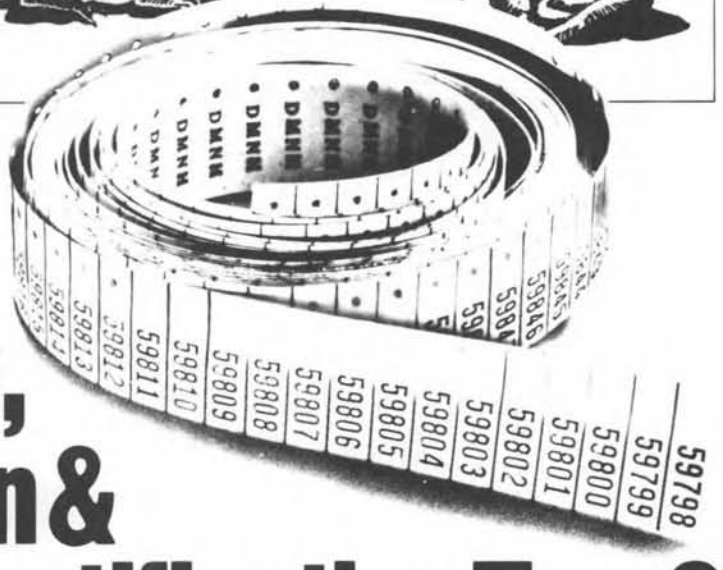
DISTRIBUTION OF THE GENUS *Rana* IN SOUTHWESTERN SAUDI ARABIA

The Kingdom of Saudi Arabia covers an area of more than two million square kilometers and represents the largest part of the Arabian Peninsula. The western coastal plain (Tihamah) on the Red Sea is narrow in the north, widening irregularly toward the south with a maximum width of about 40 km near the city of Jizan. It is a hot, dry plain crossed by dry river channels (wadi) that periodically flood with drainage from nearby mountains. The Tihamah is bounded on the east by the escarpment of the Hijaz Mountains, which rise abruptly to a height of over 3300 meters at Soodah Mountain near Abha. These mountains of the southwest have the coolest temperatures and the highest precipitation in the Kingdom. The rainfall of 250 to 500 mm per year supports dry land terrace farming and scattered juniper woodlands in the high mountains (Bindagji 1978). The eastern side of the Hijaz drops more gradually to the central plateau. The plateau is desert steppe with large areas of moving dunes extending to the Arabian Gulf coast. Some areas of the central plateau may go without rain for several years (Chapman 1978).



Two species of *Rana* are known from the peninsula: *Rana ridibunda* Pallas, 1771, with affinities in Europe and northern Africa, and *Rana cyanophlyctis ehrenbergi* Peters, 1864,

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Stop your searching. Here are those identification tags you've been looking for. Save time, money and patience simply by ordering them right now from the NATIONAL TAG COMPANY. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on both sides.

*Note: Stock tags are consecutively numbered, but the starting number will vary for each shipment. There's no printing on back side. Custom tags can get any numbering sequence desired, with or without prefix letters, plus printing on the back side (illustration above).

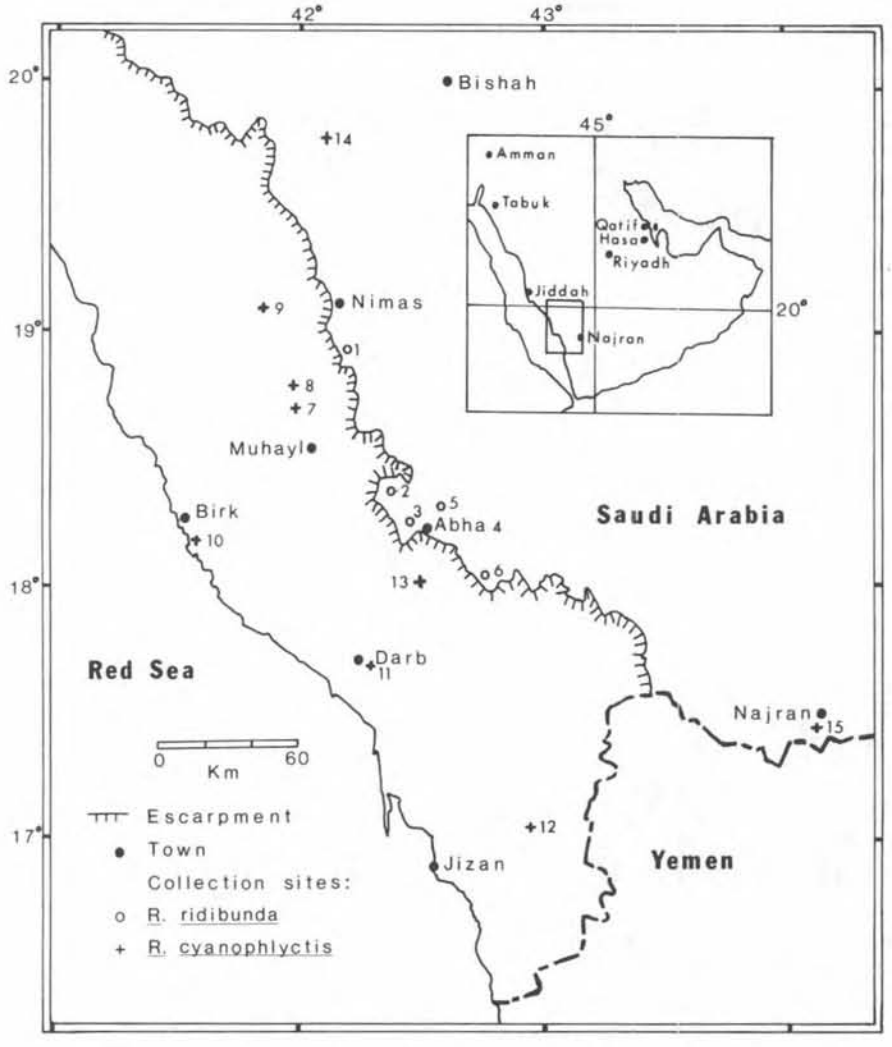

Figure 1. Map of *Rana* collecting sites for September 1983 expedition to southwestern Saudi Arabia. Map modified from the "Road Map and Tourist Resorts in the Asir Area" published by the Kingdom of Saudi Arabia and Asir Quadrangle Map, scale 1:500,000, Geographic map 217, Ministry of Petroleum and Mineral Resources, Kingdom of Saudi Arabia.

with affinities to the east in southern Asia (Arnold 1980). Collections of *Rana* from the peninsula have been limited in the past by inaccessibility to zoologists.

R. ridibunda has been reported from the eastern oasis regions (Arnold 1980; Briggs 1981; Haas 1961; Parker 1933) and the southwestern mountains of Saudi Arabia (Arnold 1980; Parker 1938). *R. cyanophlyctis* has been reported from the southwestern region of Saudi Arabia and Yemen (Anderson 1901; Arnold 1980; Boulenger 1920; Haas and Battersby 1959; Parker 1941; Schmidt 1953; Steindachner 1903).

The distribution of the genus *Rana* in Arabia is necessarily fragmented due to the spotty distribution of permanent surface water. In September of 1983 we investigated 22 aquatic sites in southwestern Saudi Arabia to better establish the ranges of these two species in the region. *Rana* were found at 15 of these (Table 1). Since September is part of the drier period, these sites represent habitats likely to retain surface water year round. At no site were the two species found to be syntopic.

R. ridibunda occurs in two widely separated areas: the mountains of the southwest (Asir) and the major oasis areas of the Eastern Province and the island country of Bahrain 26 km off the eastern Saudi coast (Fig. 1). In the Asir they are found only in high mountain wadis (valleys) above about 1900 meters, typically in places where gravel is thin and water is forced into surface pools by impervious rock ledges or in pools at the bases of waterfalls. Since these localities are high in the mountains, the seasonal flooding is not as torrential as that of the wadis at lower altitudes, which drain more extensive watersheds.

Over 1000 km northeast of the mountain populations are the three disjunct oasis populations of Al Qatif (ca. 35 km), Al Hasa (ca. 200 km), and northern Bahrain (ca. 25 km). These three natural oases are supplied by artesian karst springs dating at least to the early Pleistocene (Hötzl et al. 1978). The mountains of the southwest and the karst springs of the east may have served as refugia for relict populations of *Rana ridibunda* throughout the periodic humid and arid phases of the Pleistocene and Holocene in Arabia.

R. cyanophlyctis is confined to the lower altitudes from sea level to about 1800 meters west of the escarpment and from about 1500 to 1900 meters on the eastern slope. These altitudes are similar to those reported for Asian populations (Boulenger 1920). Typically these lower wadi systems of the southwest are subject to periodic flooding, sometimes of devastating proportions, which completely scrubs and rearranges the wadi floor.

In February of 1982 and again in February of 1983 the southwest experienced tremendous flooding that washed out numerous bridges and highways in the lower wadis. Populations of *R. cyanophlyctis* were found breeding in the pools of these wadis in September 1983, indicating that they have the ability to survive the passing floods and disperse quickly into newly formed pools.

We thank Ivan Miller (Asir National Park), Al Fadel Zakri and Abdulaziz Al Amery for their assistance in locating field sites and Mr. M. Shafi Minhas for typing the manuscript. The project was supported in part by a grant from King Faisal University.

TECHNIQUES

A SIMPLE TECHNIQUE FOR TRAPPING PRAIRIE RATTLESNAKES DURING SPRING EMERGENCE

A technique for live trapping snakes depends on an individual's design which may vary according to time of year, terrain and species sought. One technique is a modified wire funnel trap set along side drift fences or natural objects (i.e. fallen logs, rocks, walls) guiding a snake into the mouth of the funnel (Imler 1945, Gloyd 1947, Dargan and Stickel 1949, Fitch 1951, Fitch and Shirer 1971). Another is a wire enclosure around the mouth of a den (Hirth et al. 1969, Brown and Parker 1976). This paper reports a simple effective capture technique using sectioned, commercially available black plastic tile or tubing (10 cm in diameter) running from blocked entrances of prairie rattlesnake *(Crotalus viridis viridis)* hibernacula. The technique relies on solar heat absorption of black plastic attracting rattlesnakes during spring emergence and the ability to block off sections of tubing so rattlesnakes could not retreat.

"Rattlesnake coulee" on the Old Man River, 4.3 km south of the city limits of Lethbridge, Alberta, Canada, received its name because of regular sightings of prairie rattlesnakes over the years. Five known former rattlesnake hibernacula entrances were located during the second week of April 1983 and 1984 and "plugged" with 7.5 cm thick foam rubber shaped to firmly wedge into each entrance. In each "plug" a small hole (5 cm in diameter) was cut, through which one end of a continuous length of black plastic tubing was inserted. The tubing protruded approximately 7.5 cm beyond the foam rubber into the hibernaculum. The "plug" of foam rubber was covered with a layer of earth to ensure that no holes were present between the foam rubber and walls of the hibernaculum entrance through which rattlesnakes could escape. Tubing protruded varying lengths depending on the terrain and the depth of a hibernaculum entrance below ground surface - total lengths varied from 2.0-5.1 m. Each length of tubing was sectioned (by cutting) into approximately equal (0.6 m) lengths and then reattached by taping (sectioning facilitated confining rattlesnakes in a shorter section of tubing and later blocking their retreat into the hibernaculum). Wire fly screening taped into position blocked the terminal end of the tubing (Fig. 1).

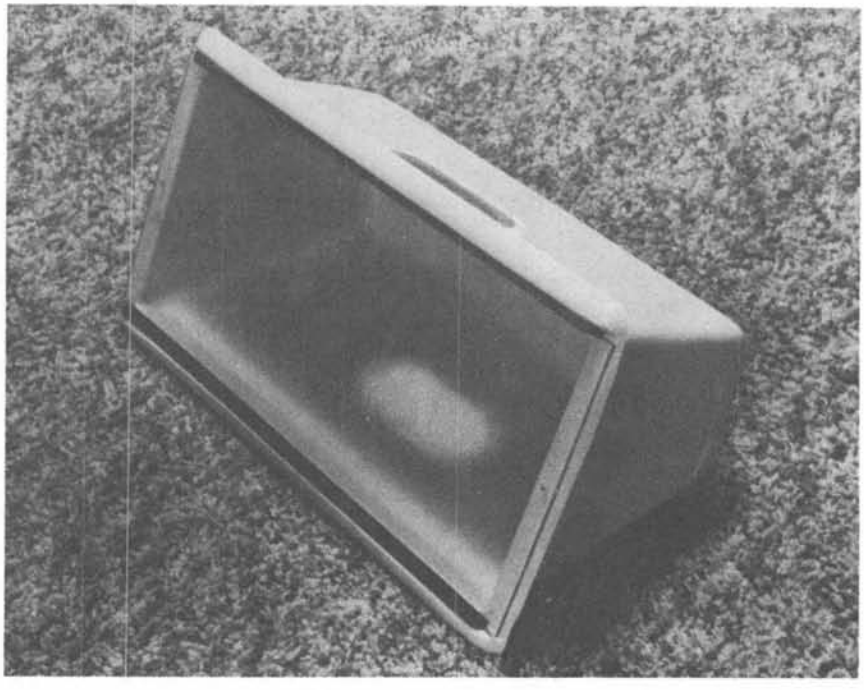

Figure 1. An exposed trap constructed of sectioned black plastic tubing and a foam rubber "plug."

The traps were checked daily and a rattlesnake's position in the tubing was easily detected by the resonating rattle. A knife was then used to quickly but carefully cut through the tape separating 2 sections - the sections separated depended on the position of the "last" (closest to the hibernaculum entrance) rattlesnake. For safety reasons, at least 60 cm distance was kept between the "last" rattlesnake in the tubing and the separation of sections. As the sections were held in place, 2 flat metal discs (12.5 cm in diameter) were inserted and taped to the respective ends of the separated sections blocking any move-

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

The Candidates

A. DALE BELCHER, Curator of Herpetology, Rio Grande Zoological Park, 1979-present. Attended University of Missouri, 1964-1968, majors in psychology, sociology, anthropology; non-degree candidate. Meramec Community College, 1970-72; A.A. Liberal Arts, minors in field biology, communication. Keeper, Senior Keeper, St. Louis Zoological Park (1972-1978). Research interest: Synecology of isolated montane crotalid populations. SSAR activities: Zoo Liaison Committee (1983-present). Publications: two papers and many popular articles.

LYNNE D. HOUCK, Research Associate (Assistant Professor), Department of Biology, University of Chicago; Ph.D., University of California at Berkeley (1977). Research interests: Sexual selection and the evolution of courtship behavior in plethodontid salamanders. SSAR Activities: Chair, Joint Annual Meetings Committee for SSAR and HL (1981-1984); Editorial Board, Journal of Herpetology (1984-1987). Publications: 11.

VICTOR H. HUTCHISON, George Lynn Cross Research Professor of Zoology, University of Oklahoma, Norman; Ph.D., Duke University (1959). Research interests: Physiological ecology of amphibians and reptiles, especially respiratory gas exchange, thermal relations and energetics. SSAR activities: Chair, Committee on Cooperation SSAR/HL (1969-1972); Joint HL/SSAR Meetings Committee (1985-present); Chair, Local Meeting Committee SSAR/HL (1972), ASIH/HL/SSAR (1984); reviewer for SSAR publications. Publications: ca. 110.

JAMES S. JACOB, Professor of Biology, Glendale Community College, Glendale, Arizona; Ph.D., University of New Mexico (1977). Research interests: Comparative morphology and physiology of reptiles and amphibians. SSAR activities: Chair of Memphis Local Committee (1981); Secretary (1982-present); Long-range Planning Committee (1983-present); Meetings Committee (1983-present). Publications: 15+.

WILLIAM W. LAMAR, Curator of Herpetology, The Caldwell Zoo, Tyler, Texas; Adjunct Assistant Professor, School of Sciences and Mathematics, The University of Texas at Tyler; M.Sc., The University of Texas at Arlington (1986).Research interests: Systematics, ecology, zoogeography, and captive management of Neotropical amphibians and reptiles. Publications: 14.

LINDA R. MAXSON, Professor, Departments of Genetics and Development and Ecology, Ethology and Evolution; Curator, Amphibians and Reptiles, UIMNH, University of Illinois at Urbana-Champaign (1983-present); Ph.D. jointly at University of California, Berkeley and San Diego State University (1973). Research interests: Molecular systematics and biogeography, speciation, amphibian phylogenetics. SSAR activities: Board of Directors (1982-1985); Editorial Board of Journal of Herpetology (1982-present). Publications: ca. 70.

NORMAN J. SCOTT, JR., Zoologist, Denver Wildlife Research Center, U.S. Fish and Wildlife Service; Adjunct Associate Professor, Department of Biology, University of New Mexico; Ph.D., University of Southern California (1969). Research interests: Systematics, ecology and zoogeography of amphibians and reptiles, especially Neotropical and southwestern United States forms; status of endangered and threatened species. SSAR activities: Editor of HL/SSAR Symposium "Herpetological Communities" (1982); Board of Directors (1982-1984). Publications: 20+ on reptiles, amphibians, monkeys and ducks.

HENRI SEIBERT, Professor of Zoology, Ohio University; Ph.D., University of Illinois, Urbana (1937). SSAR activities: Board of Directors (1962 to date); Publications Secretary (1966-1976); Treasurer (1970 to date). Publications: dozens.

Society for the Study of Amphibians and Reptiles

BALLOT

This is the official ballot of the SSAR to elect officers for 1986. All SSAR members are urged to vote. This ballot must be received no later than 15 December 1985. Please use the attached self-addressed envelope.

For President-elect (vote for one):

- ☐ Linda Maxson
- ☐ Norman J. Scott, Jr.

For Secretary (unopposed):

- ☐ James S. Jacob
- ☐ _____

For Treasurer (unopposed):

- ☐ Henri C. Seibert
- ☐ _____

For Board of Directors (Class of 1988 vote for one from each category):

REGULAR

- ☐ Lynne D. Houck
- ☐ Victor H. Hutchison

ZOOLOGICAL PARKS

- ☐ A. Dale Belcher
- ☐ William W. Lamar

ment of rattlesnakes through the tubing.

Rattlesnakes were forced to the terminal end of the tubing and into a collecting bag by manually lifting and tapping the tubing along its length (tapping was necessary because large rattlesnakes will coil, holding themselves secure even when the tubing is held vertical). The sections of tubing were then replaced and taped back into position. The rattlesnakes were taken to a laboratory for sexing, weighing, length measurements, photographing and tagging. In total, 23 rattlesnakes were captured from 3 hibernacula. No rattlesnakes died using this technique.

Originally, "funnel flaps" (made of wire fly screening and painted black) were put in entrances to the tubing and were successful in preventing retreat to the hibernacula. However, the flaps were removed because of the possibility of rattlesnakes' overheating in the black tubing (checking traps more than once daily and/or using perforated tubing might prevent this). With the flaps removed, rattlesnakes were free to move back into the hibernacula. Although different coloured tubing could be used for this trapping technique, the low cost and availability of commercial black plastic tubing were the reasons for its use.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

CAUDATA

AMBYSTOMA TIGRINUM (Tiger Salamander). **BEHAVIOR.** Defense posturing by salamanders is well documented by Brodie (1977. Copeia 1977(3):523-535). The following is submitted as a case history. On 22 October 1978 at Squaw Creek National Wildlife Refuge, Holt County, Missouri, defense posturing was observed in a small *Ambystoma t. tigrinum* measuring about 170 mm in total length. The individual was crossing a gravel road when tail waving was first elicited by the approach of a motor vehicle, and again upon the approach of two persons on foot. At this time the tail was held almost vertically and waved back and forth, the hind legs were extended lifting the posterior portion of the body higher into the air, and the neck was strongly flexed depressing the rostrum into the ground. After several bouts of stimulation by the observers, the body was severely curved, assuming a u-shaped configuration, and the tail was lowered (Fig. 1).

Figure 1. Antipredator response assumed by *Ambystoma tigrinum*.

The time of occurrence was approximately 0900 h CST, and associated temperatures were 16° C (soil) and 14.6° C (air at 25 mm). The sky was overcast and the wind from the northwest at 8 to 16 km per hour.

Another *A. tigrinum* observed on the Refuge the same day did not respond with similar behavior. However, on 25 October 1981 during a visit to the same locality and under similar weather conditions, a larger tiger salamander was observed to exhibit the tail waving.

It is interesting to note that during fall diurnal movements two of three specimens from this locality responded with defense posturing and that tail waving was observed prior to physical contact, in the first case, probably in response to visual and/or vibratory cues.

Thanks to Dr. E. D. Brodie, Jr. for commenting on an earlier draft of this note.

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th Street and Rainbow Boulevard, Kansas City, Kansas 66103, U.S.A. ●

EURYCEA LUCIFUGA (Cavé Salamander). **BEHAVIOR.** A specimen of *Eurycea lucifuga* was captured in Onyx Cave, Mark Twain National Forest, 4 km S of Roaring River State Park, Barry County, Missouri, on 27 June 1974. Later, when the specimen was placed on a dampened rock for photographic purposes, it elevated the anterior portion of its body in an exaggerated manner, exposing its gular region. The movement appeared very robotic in nature, and the posture was held immobile and apparently quite rigid for several seconds. A number of attempts, by tactile stimulation, to elicit repetition of this behavior did not result in a response exhibiting the

same degree of spontaneity or intensity of the first. The accompanying photograph (Fig. 1) was taken after the initial display, but the body position approximates that of the observed posture.

It may be important to note that this behavior was not observed under controlled conditions nor at initial contact with the salamander, but only after capture, several hours of confinement in a moist collecting tube, and then exposure to a new regime of light, heat and humidity. These variables may have triggered the response, however, specimens of *Plethodon glutinosus* and *P. dorsalis* captured at the same locality and photographed at the same setting, immediately after the *E. lucifuga*, did not respond in the above manner.

Figure 1. The low intensity rigid posturing exhibited by a specimen of *Eurycea lucifuga*.

Brodie (1977, Copeia 1977(3):523-535) extensively documented defense posturing in salamanders, and presented a photograph and described an antipredator posture for *E. lucifuga*. It included coiling of the body and elevation of the tail. The low intensity, rigid posturing, with elevation of the anterior portion of the body observed in our specimen may be another form of defense posturing by this salamander. It is apparently very similar to the infrequent behavior observed in *Aneides flavipunctatus* which was postulated to be defensive in nature by Jones (1984. SSAR Herp. Review 15(1):17).

Thanks to Dr. E. D. Brodie, Jr. for commenting on an earlier draft of this note.

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th Street and Rainbow Boulevard, Kansas City, Kansas 66103 and **LON C. BALCH,** Babler State Park, Chesterfield, Missouri 63017, U.S.A. ●

EURYCEA LUCIFUGA (Cave Salamander). **COLORATION.** Neither Hensley (1959. Publ. Mus., Mich. State Univ. 1(4):133-159) nor Dyrkacz (1981. SSAR Herp. Circ. No. 11:1-31) listed albinistic specimens of *Eurycea lucifuga*. A leucistic specimen of this species was collected in Mauss Cave, 21 km WNW of Camdenton, Camden County, Missouri, on 28 September 1968 by an Ecology Class from the University of Missouri-Kansas City. The specimen exhibited normal eye color but only two small patches of normal skin pigmentation on its left flank and dorsum of the tail. It measured about 60 mm in total length, with a tail length of 20 mm, extremely short for this species, and had probably only recently metamorphosed.

Minckley (1959. Herpetologica 15(4):240) described a predominantly white specimen of this species, and cited references to several other color variants from the western periphery of the Ozark Plateau Region. The Camden County locality is near the northern edge of that Region.

The speciman was apparently not preserved and has been lost.

Submitted by **DONALD D. SMITH,** Department of Pathology and Oncology, University of Kansas Medical Center, 39th Street and Rainbow Boulevard, Kansas City, Kansas 66103, U.S.A. ●

SERPENTES

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake). **COLORATION.** Amelanistic specimens of *Cemophora coccinea* previously have been reported from Rockingham Co., North Carolina (Brimley 1942. Carolina Tips 5(1):3) and Clayton Co, Georgia (Herman 1983. SSAR Herp. Review 14(4):119). On 9 March 1985, an amelanistic adult female was collected on the Katharine Ordway Preserve/Swisher Memorial Sanctuary, ca. 8.5 km E and 1.5 km S of Melrose, Putnam Co., Florida. The snake, which measured 450 mm (397 mm SVL) with a mass of 13.5 g, was first captured at 2350 h in a pitfall trap on the inside of a continuous terrestrial drift fence encircling an intermittent pond (nicknamed Breezeway pond, 0.1 km S Smith Lake, Putnam Hall Quadrangle) in longleaf pine-turkey oak sandhills habitat.

The dorsal pattern and coloration of the snake resembled the description of the two previously reported specimens. The parts of the dorsum that are normally black in *Cemophora* and the tip of the tongue were pale white, and the eyes were red. The dorsal saddles were reddish-pink and narrow; there were 23 complete saddles on the body and one complete and 4 partial saddles on the tail. No other *Cemophora* have been observed in the vicinity of the drift fence since it was erected in late January, though the species is reportedly not uncommon in the area (R. Franz, pers. comm.).

COLUBER CONSTRICTOR PRIAPUS (Southern Black Racer). **FOOD.** At 1515 h on 22 January 1984,7.8 km S Monroe Station on State Highway 94, Monroe County, Florida, I observed an adult (SVL = 936 mm; mass = 159 g) female *Coluber constrictor* carrying a small rodent. When first observed, the snake moved slowly in mid-roadway, head elevated ca. 15 cm above the substrate. The prey struggled feebly as it was maneuvered into a position to facilitate swallowing. The snake made no attempt at constriction and completed swallowing in ca. four min. At that point, I captured the snake, measured, palped and released it. The prey proved to be a juvenile rice rat (*Oryzomys palustris coloratus;* mass = 10.2 g) less than 30 days old (based on tooth eruption pattern and ossification of the frontoparietal region).

C. constrictor is well known for its catholic diet, which includes an impressive array of small mammals (see summary in Fitch 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351-468). Despite a variety of dietary studies and anecdotes, *O. palustris* is not reported as prey. *O. palustris* is a cricetid rat abundant in marshy habitats of the southeastern U. S. (Pournelle 1950. J. Mammal. 31:310-319; Ivey 1959. J. Mammal. 40:585-591; Sharp 1967. J. Mammal. 48:557-563), whose morphology and physiology allow it to lead a semi-aquatic existence (Esher et al. 1978. J. Mammal. 59:551-558). The site of this observation is a cypress *(Taxodium distichium)* swamp, a habitat where *C. constrictor* is typically rare, being usually restricted to adjacent larger hammocks that have substantially higher ground. However, the elevated roadbed (of Highway 94) seems to provide enough area for *C. constrictor* nest and refuge sites to support a substantial population because one can observe three to six adult *C. constrictor* per kilometer in the vicinity of this site on warm, sunny days. Because rice rats often nest along similar water-edge habitats (Ivey 1959; Sharp 1967), they appear to be accessible to *C. constrictor* in this juxtaposition of swamp and man-made terrestrial habitats.

Hank Setzer (Florida State Museum, Gainesville) kindly identified and aged the rat.

Submitted by **MARC P. HAYES,** Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124, U.S.A. ●

CROTALUS ATROX (Western Diamondback Rattlesnake). **COLORATION.** In the spring of 1984, a female *Crotalus atrox* (575 mm SVL) was collected at Fort Sam Houston, San Antonio, Bexar Co., Texas and donated to the San Antonio Zoo by Raymond Cross.

The snake has a gold-brown dorsum which gradually changes to a cream colored venter. There is a dark brown mid-dorsal stripe, varying in scale width, that runs down the entire body, excluding the tail. The tail is black dorsally and the lateral and ventral surfaces are white and cream respectively with black mottling throughout. In front of each eye is a light stripe that extends down to the mouth.

This type of color and pattern has been recorded before in *C. atrox* (Gloyd 1958. Bull. Chicago Acad. Sci. 10:185-195; Karges 1979. Trans. Kansas Acad. Sci. 82(4):205-208; Holmback 1981. Herp Review 12:70; Tennant 1984. Snakes of Texas, 463 pp.). An interesting note is that despite the extensive range of *C. atrox* throughout southwestern North America, all of these specimens have been from localities in south central Texas.

This female will be used for breeding purposes at the zoo with a similarly aberrant male already in the collection.

Submitted by **ERIK HOLMBACK,** Reptile Department, San Antonio Zoological Gardens and Aquarium, San Antonio, Texas 78212, U.S.A. ●

CROTALUS MOLOSSUS (Blacktail Rattlesnake). **ANOMALY.** A male *Crotalus molos-*

sus captured 11 May 1980 on the Rosillo Ranch, 20 km north of Panther Junction (Big Bend National Park), Brewster County, Texas, has no vestige of a rattle. The tail terminates abruptly (Fig. 1) and shows no scarring or signs of previous trauma. Total length is 934 mm with the tail having 26 subcaudal scales and measuring 64 mm (6.9% of the total body length). Wright and Wright (1957. Handbook of snakes of the United States and Canada, Vol. II, Comstock Publ. Assoc.: pp. 565-1105) noted that the tail of *C. molossus* is relatively short, seldom measuring over 7.1% of the total body length and rarely with more than 27 subcaudals in males.

Klauber (1972. Rattlesnakes, their habits, life histories, and influence on mankind, 2nd Ed., Vol. 1, Univ. Calif. Press: 740 pp.) stated that the most common cause of missing rattles is trophy hunting by man with subsequent recovery and survival of the traumatized snake. However, four cases of missing rattles were thought to be congenital defects, including a *C. cerastes* and a *C. pricei* with no vestiges of rattles.

Since measurements and scalation of our specimen are so close to reported maxima, and there is no sign of trauma, we conclude that the anomaly is congenital, and due to the lack of the radio dense style or shaker (Fig. 2).

Figure 1. Tail of *C. molossus* (BWMC 1502) showing no sign of scarring or trauma.

Figure 2. Radiograph of tail of *C. molossus* (BWMC 1502) illustrating lack of a radiodense style or shaker. Inset is the tail of a normal rattlesnake. This structure is normally formed by the fusion of several terminal vertebrae, a process only suggested in the anomalous specimen (arrow).

The specimen is deposited in the Bobby Witcher Memorial Collection (BWMC 1502), housed at Avila College, Kansas City, Missouri 64145.

PARMERLEE, JR.,** Department of Natural Sciences, Avila College, 11901 Wornall Road, Kansas City, Missouri 64145, U.S.A. ●

DASYPELTIS SCABRA (African egg-eating snake). **FEEDING.** Gans (1974. Biomechanics. J.B. Lippincott Co.) discussed the adaptations that make *Dasypeltis* ssp. successful obligate egg eaters, in particular the capacity of these snakes to swallow extremely large eggs. An example given by Gans was of an individual with a head width of 10 mm swallowing an egg 44.0 mm in diameter. Rabb and Snediger (1960. Copeia 1961:59-60) fed an African egg-eating snake (mass, 180 g; total length, 850 mm) chicken eggs that averaged 51.2 g, 54.7 mm in length, and 41.4 mm maximum width. On 10 October 1981, the following observations on the feeding of a female African egg-eating snake *(Dasypeltis scabra)* were made at the University of Oklahoma Animal Behavior Laboratory.

The snake (mass, 52.0; total length, 630 mm; head width, 10 mm) was given a freshly laid, domestic duck egg (mass, 70.4 g; volume, 69.0 ml; length 65.0 mm; maximum width, 46.0 mm) at 0730 h. It immediately examined the egg and began to swallow it at 0745 h. One hour later the egg was approximately 30% ingested (Fig. 1). The egg was completely swallowed and being cracked 2.5 h later, and reduced to its final size (Fig. 2) after an additional hour (4.5 h after it was first given to the snake). The snake was quietly checked every 30 min rather than watched continuously. Despite this, the snake was sufficiently disturbed to temporarily cease feeding when watched. Thus, the time taken to swallow the egg was probably increased by observer disturbance. The shell was found disgorged at 1600 h; its measurements were: length, 5.5 mm; maximum width, 3.2 mm, and it exhibited the characteristic non-elliptical "boat" shape described by Gans. A total of

Figure 1. Position of egg 1 hour after the snake first began to swallow it.

Figure 2. Position of egg 3.5 hours after the snake first began to swallow it.

40.6 g (38.0 ml) of the content was extracted and consumed by the snake, an amount equivalent to 78% of the snake's initial body mass. The following day a portion of the meal was regurgitated and the snake's skin around the throat sagged from the previous day's stretching. These observations demonstrate an African egg-eating snake's ability to consume exceptionally large eggs.

I wish to thank Mark A. Paulissen and Dr. Charles C. Carpenter for their suggestions on this manuscript.

Submitted by **JAMES J. KRUPA,** Department of Zoology, 730 Van Vleet Oval, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. ●

HYPSIGLENA TORQUATA DESERTICOLA (Desert Night Snake). **BEHAVIOR.** Many species of snakes are known to exhibit unusual postural and physiological responses such as death feigning, head cocking, defecation, cloacal sac discharge, erratic crawling, and body bridging in the presence of ophiophagous snakes (see reviews by Gehlback 1970, Herpetologica 26:24-34; Carpenter and Gillingham 1975, Herpetologica 31: 293-302; Carpenter and Ferguson 1977, *In:* Gans and Tinkle, Biology of the Reptilia, Vol. 7, pp. 335-554; Weldon and Burghardt 1979, J. Chem. Evol. 5:141-151). This note desribes several of these behaviors displayed by a desert night snake when placed in the cages of two ophiophagous snakes.

On 30 May 1984 I placed a ca. 45 cm night snake into the cage of a ca. 65 cm western yellow-bellied racer, *Coluber constrictor mormon.* The night snake immediately began flicking its tongue, and assumed a slow, stiff crawl with the lateral coils of its body raised 0-1 cm above the artificial turf substrate. About 60 sec later the tongue flicks subsided, and the tail cocked upward at a 45° angle from the cloaca. The cloacal sac was slowly everted through the cloaca, discharged, and withdrawn. The tail remained erect for about 120 sec as the night snake slowly crawled along the edge of the cage, and during the latter half of this period the head was cocked upward at a 30° angle. Throughout this incident the respiratory rate of the snake was rapid, about 70 per min. After about five min, the racer showed no apparent interest. When touched with a stick, the night snake responded with rapid erratic escape movements.

I removed the night snake from the racer cage and placed it into the cage of a ca. 90 cm California kingsnake, *Lampropeltis getulus californiae.* The night snake crawled semirigidly along the side of the cage, and was

quickly grasped 30 sec later near the cloaca by the kingsnake. The night snake initially attempted to burrow into the cedar shavings substrate, but soon ceased struggling. As the kingsnake slowly engulfed its prey tail first, the night snake was virtually motionless, with occasional feeble movements, and appeared to be feigning death. The entire feeding process terminated within 180 sec.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). **REPRODUCTION.** A fresh road kill (UOMZ 35373) was collected on 20 June 1984 two mi E of Hugo, Choctaw Co, Oklahoma near the junction of state highways 70 and 93. The gravid female measured 104 cm (snout-vent)/119 cm (total length) and contained 21 eggs near term with shells formed. Clutch size exceeds by four the maximum of 17 listed by Fitch (1970, Misc. Publ. #52, Univ. Kansas, Mus. Nat. Hist.).

Submitted by **CHARLES C. CARPENTER,** Department of Zoology, University of Oklahoma, Norman, Oklahoma, U.S.A. ●

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). **REPRODUCTION.** Dystocia (difficulty in delivery of eggs or young) is common among captive reptiles, particularly chelonians. Mummified fetuses are apparently less common but a case has been reported in *Thamnophis sirtalis* (Frye 1981. Biomedical and Surgical Aspects of Captive Reptile Husbandry. Vet. Med. Publ. Co. pp. 297-307).

On 27 May 1983 we captured a large female *Nerodia erythrogaster transversa* measuring 827 mm S-V, by the Rio Sabinas at San Juan de Sabinas, Coahuila, Mexico. Its abdomen was greatly distended and contained several large, hard, palpable masses. The snake was in poor condition, obviously emaciated, and died three days later. Upon dissection we found six granular masses (Fig. 1), still in the oviduct, but apparently the cause of a severe case of peritonitis. Radiographs showed three of these masses to contain mummified fetuses (Fig. 2), and three, probably individual infertile ova, showed no skeletal fetal remains.

The specimens are deposited in the Bobby Witcher Memorial Collection (BWMC 2144), Avila College, Kansas City, Missouri.

Figure 1. Six ovarian masses dissected from an oviduct of *N. erythrogaster*. The small one at the lower left has been cut in half, and the one at the lower right has been partially teased apart.

The authors thank the Direccion General de Flora y Fauna Silvestres, Mexico, D. F., for permission to collect herpetological specimens in Mexico, and Dr. J. A. Mauck, D.V.M., Farview Animal Hospital, Independence, Missouri, for radiographs of the ovarian masses.

Figure 2. Radiograph of one of the ovarian masses showing skeletal remains of mummified fetuses.

TANTILLA GRACILIS (Flat-headed Snake). **ALBINO.** Juvenile specimen (snout-vent = 88 mm, total length = 106 mm) collected 13 June 1984 where many normally colored individuals have been observed over the past 33 years. Specimen was beneath a slab of limestone on the side of a limestone bluff in open forest near Briar Creek, ca. 5 mi NW University of Oklahoma Biological Station, Marshall Co, Oklahoma. Melanin was completely lacking, no head pattern apparent, the eyes pink with a slight pinkish tinge to the belly. It was maintained in captivity for 40 days, then preserved and placed in the collections of the Stovall Museum of Science and History of the University of Oklahoma (UOMZ 35372).

Submitted by **CHARLES C. CARPENTER,** Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. ●

TROPIDOCLONION LINEATUM ANNECTENS X TEXANUM (Central X Texas Lined Snake). **COLORATION.** Three amelanistic partial albino *Tropidoclonion lineatum* have previously been reported from Texas by Hensley (1959 Publ. Mus., Mich. State Univ. 1(4):133-159), Dyrkacz (1981, SSAR Herp. Circ. 11) and Tennant (1984, Snakes of Texas, Texas Monthly Press, Austin).

An additional, amelanistic partial albino *Tropidoclonion lineatum annectens* X *texanum* was collected on 21 August 1984 by Lynn Madewell in a residential area of Haltom City, Tarrant Co., Texas. The juvenile male was donated to the Fort Worth Zoological Park and at the time of capture had a total length of 108 mm.

In life, the specimen had a ground color of light tannish pink with darker pink specks bordering a white middorsal stripe and cream lateral stripes. The eyes were pink and the normally black ventral half-moons were dark pink.

The collector reported that an adult specimen of similar coloration had previously been killed by a neighbor, but was discarded.

The juvenile specimen was maintained in captivity for several months and then deposited in the Vertebrate Collection, University of Texas at Arlington (UTACV #10055).

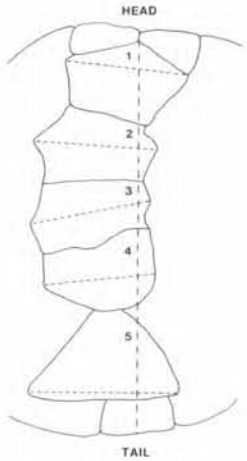
TESTUDINES

GEOCHELONE ELEPHANTOPUS VANDENBURGHI (Galapagos Giant Tortoise: Volcan Alcedo Race). **MORPHOLOGY.** Minor shell anomalies occur frequently in the large population of 3,000-5,000 Galapagos tortoises on Volcan Alcedo, a large shield volcano on Isabela Island in the Galapagos Archipelago. Deformities of a large magnitude are seldom observed among adult tortoises in the wild since such individuals die at a relatively young age. We report such an individual to document its occurrence in a wild population and to speculate upon the causes of the deformity.

On 21 June 1984, an adult female Galapagos tortoise was found with an extremely deformed carapace near the sulphur beds on

the southwest side of Volcan Alcedo, Galapagos Islands. The carapace, which bulged radically to the left, was 92.0 cm long and 109.6 cm wide. A line drawn from the nuchal notch to the center of the rear marginal scute afforded measurements of the deviation of vertebral scutes from center (see Fig. 1). Width measurements of the five vertebral scutes and the distance from the right edge to the center line are given as follows: (1) 27.0 cm, 10.5 cm; (2) 23.2 cm, 3.5 cm; (3) 23.6 cm, 2.7 cm; (4) 20.6 cm, 3.5 cm; and (5) 23.9 cm, 9.2 cm.



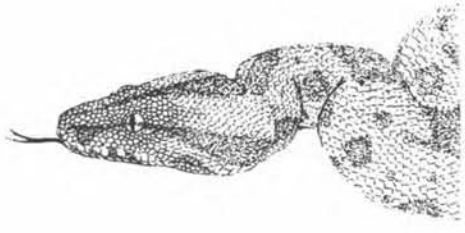


Figure 1. Drawing of deformed Galapagos tortoise carapace showing deviation of vertebral scutes from the midline of the carapace.

The deformity may be the result of (1) a congenital deformity of a genetic and/or teratogenic nature, (2) a post-zygotic pathological condition (e.g. tumor), (3) an injury sustained from a fall or falling rock, or (4) an injury inflicted by a feral burro *(Equus asinus)* when the tortoise was young. Although the exact cause of this deformity remains speculative, the injury from a burro hypothesis merits special attention.

In a recent study of tortoise nesting success on Volcan Alcedo, Fowler de Neira and Rose (1984. Copeia 1984:702-707) found that 18.2% of 88 nests on the caldera floor were disturbed by feral burros. Many hatchlings undoubtedly die as a result of this disturbance, but the deformed tortoise may have survived such an incident with sublethal injuries. Authorities are presently eradicating the feral burros on Volcan Alcedo in an effort to save the tortoise from competition for food and interference in nesting success.

Submitted by **FLOYD E. HAYES** and **KENT R. BEAMAN,** Department of Biology, Loma Linda University, Riverside, California 92515, U.S.A. ●

LEPIDOCHELYS OLIVACEA (Olive Ridley Sea Turtle). **REPRODUCTION.** Olive ridleys were tagged at Punta Raton, Honduras (13° 16' N, 87°31' W) on the Gulf of Fonseca during the 1984 nesting season. The internesting intervals recorded between egg layings are listed in Table 1. Almost half the internesting intervals were 15 to 17 days long. This is in accord with data reported for olive ridleys nesting in Surinam where 17 days was the most common internesting interval (Pritchard 1969. Sea turtles of the Guianas. Bull. Fla. State Mus., 13:85-140; Schulz 1975. Sea turtles nesting in Surinam. Zoologische Verhandelingen, uitgegeven door het Rijksmuseum van Natuurlijke Historie te Leiden, 143:1-144.) In contrast, on the west coast of Mexico, olive ridleys follow a 28 day internesting cycle (Marquez 1982. pp. 153-158, *In:* Biology and Conservation of Sea Turtles, Smithsonian Institution Press).

Table 1. Internesting intervals and frequencies between recorded successful nests of *Lepidochelys olivacea.*

At Punta Raton, one turtle bearing a monel metal tag on each front flipper laid 93 eggs on 2 October 1984, and 96 eggs 10 days later on 12 October. She was seen nesting again only four days later on 16 October.

MALACLEMYS TERRAPIN TERRAPIN (Northern Diamondback Terrapin). **BEHAVIOR.** Juvenile diamondback terrapins with shell lengths from 2.5 to 7.5 cm were observed over a three-year period from 1979 to 1981 at Barneget Bay, Beach Haven, New Jersey. These *M. terrapin* used surface debris to conceal themselves on a 4-5 acre tidal mud flat. They were always found at low tide, ca. 100 yards from the water's edge on well-drained ground.

From 30 May 1979 to October 1981, 12 observations were made of juvenile *M. terrapin* hiding under accumulated surface debris and matted *Spartina* grass. In early June 1979, one specimen was discovered under a piece of board. On 30 May 1980 two were found under a piece of a wooden chair seat on the same mud flat. On 4 July 1980 one specimen was discovered hiding under a dense, low-growing blueberry (*Vaccinium* spp.) bush. Two more were found by rolling back matted sections of *Spartina* grass that same year.

In early July 1981, two were found under large rocks, and another by rolling back matted *Spartina* grass. In September 1981 one was located under a large rock and a second under matted *Spartina* grass. In October 1981 two more were found under rocks.

Surface debris and matted *Spartina* grass apparently offers adequate cover for predator avoidance and permits thermoregulation. This hiding behavior has not been described previously for *M. terrapin.*

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be

adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

PSEUDACRIS STRECKERI STRECKERI (Strecker's Chorus Frog). USA: TEXAS: Somervell Co: 12.1 km NE Glen Rose on US 67 at Jct. county rds. 406 and 407. 5 May 1985. C. T. McAllister. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 4576-4578). New county record filling a hiatus between Bosque, Erath and Hood counties in the northcentral Brazos River watershed (Raun and Gehlbach. 1972. Amphibians and Reptiles in Texas. Dallas Mus. Nat. Hist. Bull. No. 2).

REPTILE CAGES

Designed with your needs in mind.

Desirable features of Herp-Huts:

- Should never have to be replaced.
- Molded in one piece of durable fiberglass, no seams, all corners rounded.
- Smooth finish facilitates easy cleaning and sterilization.
- Top front ridge, ideal for clamping heat lamp, if desired.
- Two vented louvers per cage (standard), designed to prevent scratches to animals and entrance of flies. Side or top mount possible.
- Side mounted vent plates make top/bottom interchangeable, creating pitch alternatives.
- Sloping front for easy viewing.
- Special vertical ridges on either side of cages "A" & "B" minimize possibility of small snakes getting wedged or escaping.
- Design suitable for reptile houses, mobile reptile exhibits, and reserve cages.
- ★ **Newest Option:** Feature requested - Hingeable front door with or without 5 inch safety glass shield.
- Traditional sliding glass front accessibity.

A New Approach to an Old Concept

Herp - Huts currently available in four standard sizes and colors: Blue, Aqua, Beige, White

Pictured:

Cage A: 16¼" W X 7½" H X 6¼" D $35.00
Cage B: 22¼" W X 9¾" H X 11" D $45.00
Cage C: 30¾" W X 16" H X 17¾" D $90.00
Cage D: 42½" W X 19¾" H X 24" D $125.00

DISTRIBUTIONAL RECORDS OF AMPHIBIANS AND REPTILES FROM THE STATE OF MEXICO

Field work in the state of Mexico has yielded seven new state records as well as new localities within the area, which are presented below.

Preserved specimens are deposited in the collection of Vivarios y Colecciones de la Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México (ENEPI). Oscar Sanchez-Herrera verified the identities of the specimens.

LEPTODACTYLUS MELANONOTUS. Bejucos (18°45'N, 100°27'W), 578 m. 18 February 1983. J. L. Camarillo. (ENEPI 502-503). First state record (Smith, H. M. and R. B. Smith 1976. Synopsis of the Herpetofauna of Mexico, Vol. IV, John Johnson, North Bennington, Vermont).

PHYLLODACTYLUS LANEI RUPINUS. Nuevo Santo Tomás de Los Plátanos (19°10'N, 100°15'W), 1380 m. 28 May 1983. J. L. Camarillo. (ENEPI 700). Easternmost record (Dixon, J. R. 1964, New Mexico State Univ. Sci. Bull. 64-1:1-139) and second from the State (Camarillo 1983. Bull. Maryland Herp. Soc. 19:39-46).

ANOLIS NEBULOSUS. Bejucos. 4 July 1981. J. L. Camarillo. (ENEPI 308); Nuevo Santo Tomás de Los Plátanos, 26 May 1983. O. Sánchez-H., (ENEPI 702). Tingambato (19° 05'N, 100°16'W); 1230 m. 22 June 1981. O. Sánchez-H. (ENEPI 284) 19 February 1983. J. L. Camarillo. (ENEPI 518) 100 km W Chalma (Camarillo 1983. ibid).

CTENOSAURA PECTINATA. Nuevo Santo Tomás de Los Plátanos. 25 September 1983. L. Alcantar. (ENEPI 710). 50 km N of Bejucos (Caramillo 1983. ibid).

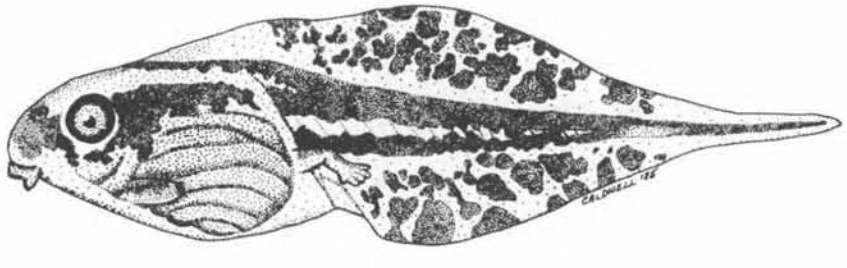
SCELOPORUS PYROCEPHALUS. Bejucos. 25 June 1982. J. L. Camarillo. (ENEPI 662-663); 28 September 1982. J. L. Camarillo. (ENEPI 416-417); 25 February 1983. J. L. Camarillo. (ENEPI 665); 4 July 1983. J. L. Camarillo. (ENEPI 310). First state records (Smith and Smith 1976. ibid. Vol. III).

HELODERMA HORRIDUM HORRIDUM. Tingambato. 19 February 1983. L. Alcantar and J. P. Carricart. (ENEPI 533). 35 km WNW Temascaltepec (Bogert, C. M. and R. Martín del Campo 1956. Bull. Amer. Mus. Nat. Hist. 109-1:1-238).

BOA CONSTRICTOR IMPERATOR. Tingambato. 5 February 1983. T. Altamirano, (ENEPI 512); Bejucos. 20 August 1983. J. L. Camarillo and R. Aguilor. (ENEPI 703). First state records (Smith and Smith. 1976. ibid. Vol. III).

LEPTODEIRA MACULATA. Bejucos. 22 June 1983. J. L. Camarillo. (ENEPI 686). First state record (Smith and Smith 1976. ibid. Vol. III).

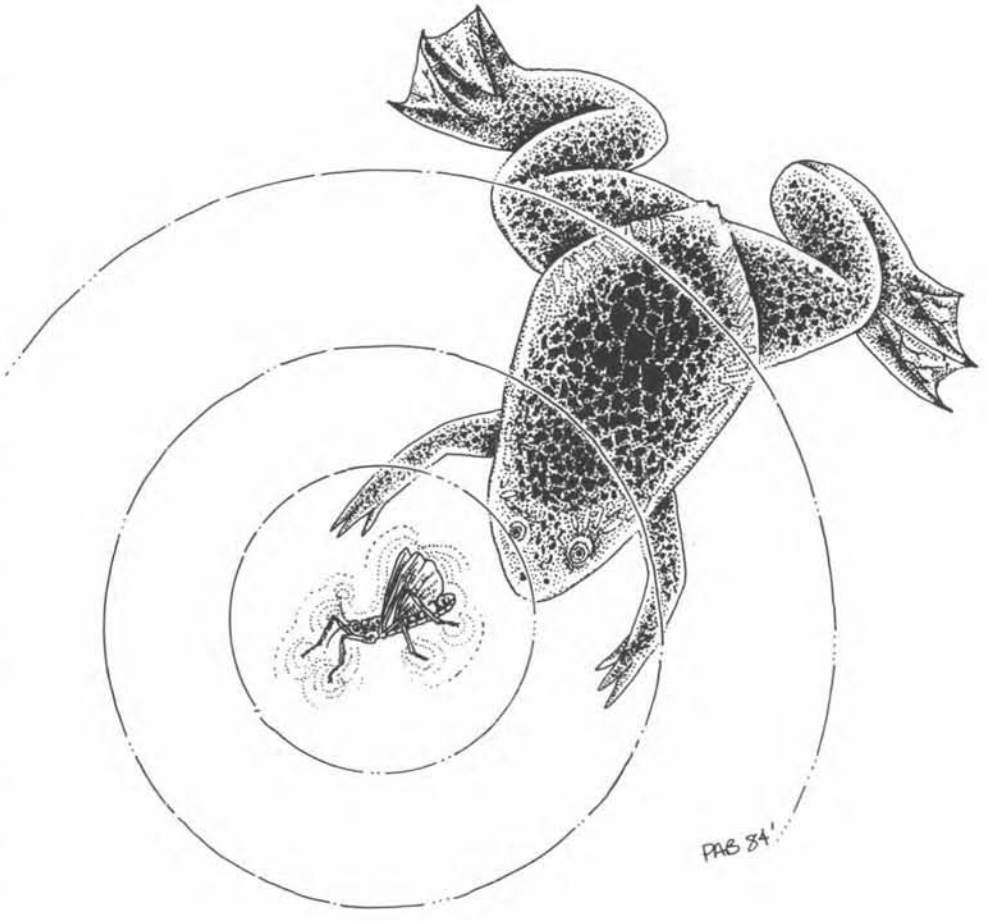
OXYBELIS AENEUS. Tingambato. 19 February 1983. L. Alcantar. (ENEPI 534). First state record (Smith and Smith 1976. ibid. Vol. III).



TRIMORPHODON TAU LATIFASCIA. Bejucos. 26 February 1983. A. Gonzalez, (ENEPI 681). First state record (Smith and Smith 1976. ibid. Vol. III).

SALVADORA MEXICANA. Bejucos. 27 June 1982. J. L. Camarillo. (ENEPI 670); 22 June 1983. J. L. Camarillo. (ENEPI 685). 40 km S Zacazonapan (Camarillo 1983. ibid).

LEPTOTYPHLOPS GOUDOTI BAKEWELLI. Tingambato. 5 February 1983. J. P. Carricart. (ENEPI 492). First state record (Smith and Smith 1976. ibid. Vol. III).



This work was supported in part by funds from the Consejo Nacional de Ciencia y Tecnología of México (contract PCECBNA-021220 to J. L. Camarillo).

BOOK REVIEWS

The Amphibians of British Columbia, by David M. Green and R. Wayne Campbell. British Columbia Provincial Museum, Handbook 45, 1984. 101 pp. Illustrated by Keith Taylor and Brigitta M. Van Der Raay. $3.00.

A 62 page booklet bearing the same title was first published in 1943, written by the late herpetologist Clifford G. Carl. The current handbook is completely rewritten with the addition of range maps and up-to-date information. It does, however, retain some of Carl's original features, including a section on folklore with the line drawing border of frogs (or toads) on a blanket drawn by Charles Edensaw, Masset, Queen Charlotte Islands.

Preceding the species accounts is a wealth of well-researched information which includes sections on Folklore, Fossil History and Distribution, Ecology and Economics, and a good section on Care of Captives — missing from Clifford Carl's booklet as amphibian pets were rarely popular in those days.

The Province of British Columbia has a great diversity of terrain. There are mountains, dense forests, valleys with rich vegetation, and desert-like areas. There is also the seashore, and crystal-clear mountain lakes and streams. With the infinite variety of landscape comes a diversity of amphibians. Nineteen species are known to occur in British Columbia.

The species accounts begin with general information on salamanders — breeding, regeneration, and a key to the eight species of adult salamanders in the province. Some interesting ones include the rough-skinned newt *(Taricha granulosa),* which, when threatened, will arch its back, bringing its tail and head up to expose its bright orange belly. The Pacific giant salamander *(Dicamptodon ensatus),* at a length of about 300 mm, is British Columbia's largest salamander. This rather rare species, if molested, can "bark" or "yelp," and sometimes attempts to bite; neotonic individuals are common. Three kinds of plethodontid salamanders also occur in this province.

The section on frogs and toads follows the same format as that of the salamanders, with an excellent account on Voice and Social Behavior in anurans. There are 11 species of frogs and toads in British Columbia. The cascades frog *(Rana cascadee),* although it has never actually been found in British Columbia, is included because of the proximity of its known range to the British Columbia border and the possibility that it may indeed occur in that province. Some frogs, including the bullfrog *(Rana catesbeiana)* (whose French name "Ouaouaron" was misspelled in the text) and the green frog, *(Rana clamitans)* were introduced into western Canada. Two fascinating anurans are the tailed frog *(Ascaphus truei)* and the Great Basin spadefoot toad *(Scaphiopus intermontanus).* The "tail" of the male tailed frog is, of course, only an extension of the cloaca. This little creature of ancient origin has many of the most primitive features to be found among living frogs. The squat-bodied spadefoot toad, like the tailed frog, has vertical pupils. It has an enlarged tubercle or "spade" on the sole of each hind foot so it can burrow to escape the drying conditions of its desert or semi-desert habitat. The Pacific treefrog *(Hyla regilla)* and Northern chorus frog *(Pseudacris triseriata)* are also native to British Columbia.

The book has a glossary and two-and-a-half pages of Useful References which include Field Guides, Handbooks, Scientific Journals, and Societies. On the last page is a list of other handbooks in this series, including number 44, **The Reptiles of British Columbia** by Patrick T. Gregory and R. Wayne Campbell.

The Amphibians of British Columbia is an exceptionally accurate work. The manuscript was reviewed by experts — James P. Bogart, Francis R. Cook (Curator of Herpetology, National Museum of Natural Sciences, Ottawa), Fred W. Schueller (inadvertently misspelled in the book), Patrick T. Gregory, and David L. Servage. The book will be of particular interest to Americans on the west coast, and those living in states near the British Columbia border, where many of the same species are to be found.

Proceedings of the First International Colloquium on Pathology of Reptiles and Amphibians, Edited by: C. Vago and G. Matz. Publiés avec Concours du Centre National de La Recherche Scientifique. Distribués Par les Presses de Univerite l'Université d'Angers, 1983 258 pp. ISBN 2-903075-21-7.

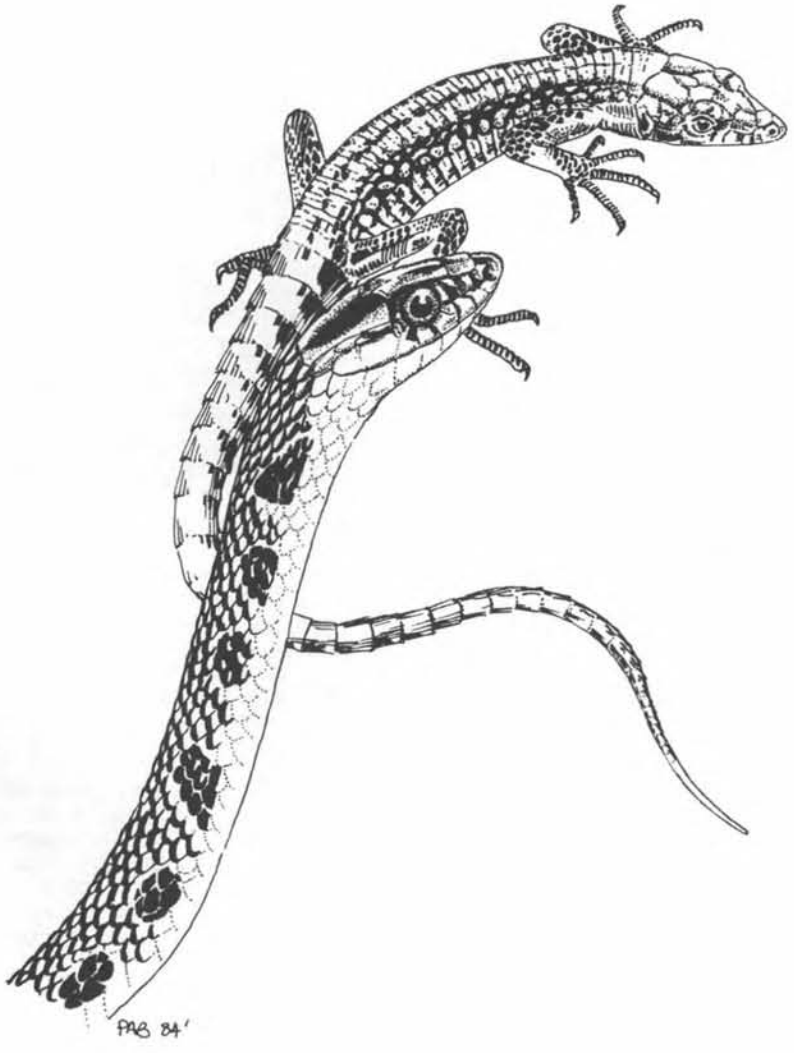
This is a published collection of papers presented at a symposium held in Angers, France, from 29 September to 2 October 1982. The book illustrates the aphorism that, unlike children, symposia should be heard and not seen. Added to the usual problems with symposia is the fact that this was a multilingual conference, and the papers are in English, French, or German. None of the English papers have summaries translated into a foreign language, and the English summaries of the French and German papers are often inadequate. An exception is the excellent and clearly written summary in the article, Developpement Somatique et Inversion Sexuelle Sous L'Action de la Temperature Chez les Embryons de Reptiles by C. Pieau.

A number of the papers which are in English were written by authors for whom English was clearly a second language. In most of these, editing was totally inadequate. The English is often clumsy and difficult to understand. Errors in spelling and syntax are numerous.

There is no introductory section explaining

to the reader the purpose of the symposium or the criteria used for acceptance of papers. Thus, we do not know to whom this book is addressed. Are the intended readers veterinary practitioners, amateur or professional herpetologists, or basic biologists? There are selected papers which might appeal to members of each of the above groups, but there is no cohesion of purpose that is apparent in the entire symposium. Instead, it seems that anyone who had something to say about a disease in a reptile or amphibian, was welcome to present his or her material.

Papers vary from individual case reports (e.g., of two-headed snakes by G. Naulleau and very randomly selected cases presented by E. Elkan) to reviews of broader topics (e.g., public health aspects of parasitic disease in snakes and amphibians by P. Hocquet) to research reports (e.g., induction of malformations in regenerating limbs of newts by the fungicide Maneb by E. Arias, N. P. Zaffaroni and T. Zavanella). The papers which present individual case reports should have been published as brief articles in various journals rather than in this symposium, which should have had a more overall sweep in its context.



A few papers stood out as clearly worthy of presentation and of better quality than most of the rest of the symposium. For example, Monocercomoniasis in Reptiles by P. Zwart, S.F.M. Teunis and J.M.N. Cornelissen was clearly written and combined empirical clinical observation, pathologic findings, and results of experimental infections. The authors clearly were competent observers of naturally occurring phenomena, and competent in experimental design. Pathological Studies on Skin Lesions in Reptiles by J. E. Cooper and L. Lawrence was a useful review even though some specific viral, parasitic and bacterial infections were omitted.

M. Balls, R. H. Clothier, et al. coauthored several papers about the effect of potentially carcinogenic agents on amphibians. These articles might be considered controversial by some, but they offer a critical review of the literature. The authors present data for their argument that amphibians, such as *Xenopus laevis*, are relatively resistant to chemical carcinogens, in contrast to claims published previously. Their discussions are one of the more useful aspects of this symposium. On the other hand, the article, Lesions Induced in *Xenopus laevis* by Exposure to Dimethylnitrosamine, by K. R. Knowles, R. H. Clothier and M. Balls is a study without adequate controls. The authors inappropriately compared their experimental results to their previous experience with normal animals. This is not justified because all of the conditions that were present during the experimental trial may not have been present during previous observations. Since these authors have been quite vocal in their criticism of technique and observations made by other authors, it behooves them to be particularly careful in their own work.

Very often the most useful aspect of a symposium is the informal communication that occurs among attendees and speakers. Furthermore, oral presentations lose much of their flavor when they are transcribed. Illustrations also suffer. It is likely that slides projected on the screen in color were much clearer than the black and white reproductions in the book, many of which are of poor quality.

In summary, there are several texts which offer much better, broader coverage of reptilian diseases. This book has some limited value in reviewing current research. I can think of no specific audience that would find the entire book useful.

Keys to the Vertebrates of Texas, by Allan H. Chaney. 1982. Caesar Kleberg Wildlife Research Institute, v-99 pp; softcover. Available: College of Agriculture, Texas A&I University, Campus Box 218, Kingsville, Texas 78363. $3.50.

After years of waiting for the "Chaney Keys" and having several editions as mimeographed copies, they have now been published by the Caesar Kleberg Wildlife Research Institute. The book is 8¼ x 10¾ inches. Keys to other groups are forthcoming. The author states that these keys were not written for the professional, but were developed for students and teacher workshops.

The **Keys to the Vertebrates of Texas** is somewhat of a misnomer, as keys to the birds are not included. The first 41 text pages are keys to the common fish of Texas followed by a one page line drawing of a composite fish. Pages 43 through 51 are keys to the adult amphibians of Texas, followed by a page of line drawings of a salamander and one page of line drawings of a frog and toad. Pages 55 through 78 are keys to the reptiles of Texas followed by one page each showing turtle, lizard and snake characteristics. Pages 83 through 99 are keys to the adult terrestrial mammals of Texas. The author suggests that the keys be used with various publications listed in the Preface. Typographical errors as well as several other lapses occur because the author was not given the opportunity to read page proofs. Accordingly, the corrections are given here. Recent changes in fish

nomenclature necessitate too many corrections to be listed in this review. It is best to await the second edition, which is in preparation.

On p. 12, the first couplet 60% should be 70%; p. 23, *O. emilieae* should be *O. emiliae;* p. 25, *N. atherinoides*, not *atherenoides;* p. 35, couplet 20 should read . . . more than 50 lateral scales, omit line; p. 39, couplet 5 is *punctulatus*, not *puntulatus;* and p. 41, couplet 4, *anisotremus*, not *anistremus*.

The amphibian keys and the line drawings (composites for the sake of brevity) are adequate.

The corrections in the reptile keys are: p. 62, should be *Cnemidophorus gularis septemvittatus;* p. 63, should be *Cnemidophorus gularis gularis;* p. 66, *disparilis* is now *microlepidotus;* p. 68, in couplet 112 between smooth and scales, omit belly; p. 69, *melanoleucus* instead of *melanoleucas;* p. 72, add 153 to last couplet; p. 73, omit *(Natrix)* in couplet 161; p. 74, change *sipedon* to *fasciata;* p. 75, couplet 171 (upper) change to *Hypsiglena torquata jani* (Texas night snake); *Trimorphodan* to *Trimorphodon;* couplet 176, omit first statement about scale rows; p. 76, couplet 183, change 185 to 186, and in couplet 184 change 186 to 185.

Mammal corrections are: p. 87, *Eutamias canipes*, not *E. speciosus;* p. 88, *Geomys breviceps* and *G. attwateri* have been inadvertently omitted from the key; p. 95, *Cervus merriami*, not *C. elephus;* p. 96, *Blarina brevicauda* should be *B. carolinensis* and *B. hylophaga*.

The above corrections are trivial compared to the real value of this publication. For the many students of the past who utilized the older keys and helped bring them to their present state, the student of the present and future should be grateful. While not aimed toward the professional, they can also benefit from the keys.

In this day of high book costs, the modest price of $3.50 for this one is a welcome relief. I would recommend it to anyone interested in the vertebrates of Texas.

Checklist and Keys to the Terrestrial Proteroglyphs of the World, by P. Golay. Spec. Publ. 'Elapsoidea' Foundation Culturelle, Geneve. i-x, 1-91, 4 figs., 1985. Obtainable from P. Golay, 1 Vieux-Moulin 1213, Onex, Switzerland, US$25.00 + $3.00 air mail.

Herpetological checklists seem to be 'in' at the moment. For many years Boulenger's Catalogues on Snakes (1893-6) and Lizards (1885-7) formed the basis of most regional and taxonomic summaries. They are now out-of-date, and although they remain an indispensible guide for taxonomic studies, they are of little regional use. A growing tide of new checklists is appearing to fill the gap.

This particular offering is of limited scope, and therein lies its advantages and disadvantages. It is less likely to contain mistakes, but then it has a more limited appeal. Due to its restricted field it would seem less likely to go out of date; however, a single major taxonomic change can undermine its whole value.

The family Elapidae has been the focus of intensive study in recent years, stimulated in no small measure by the provocative studies of Sam McDowell. Major changes in the content and relationships of proteroglyph snakes have been proposed (e.g., McDowell 1967, 1968; Savitsky 1979) and many of these have been incorporated into this Checklist. Unfortunately these are not discussed in an Introduction, and readers unfamiliar with the modern literature (much of which has appeared in diverse and obscure publications) may be surprised at some of the inclusions and omissions, e.g., the presence of the family Hydrophiidae (sea snakes) in a book on terrestrial species. This arrangement stems from McDowell's (1967) proposal that the Hydrophiinae (restricted in scope by the removal of *Laticauda*) is derived from the "Australian elapid radiation, most probably from the *Demansia* group." This relationship has been incorporated into the classification formally proposed by Smith et al. (1977).

In another revolutionary proposal that threatened taxonomic upheaval in the family Elapidae, McDowell (1968) demonstrated that the type genus *Elaps* (containing the South African species *E. lacteus* and *E. dorsalis)* was not related to other proteroglyph snakes, but had closer affinities with aparallactine colubrids. To avoid unnecessary nomenclatural chaos a successful application was made to the International Commission on Zoological Nomenclature (Opinion 1201, 1982) for the suppression of *Elaps*, the validation of the junior synonym *Homoroselaps* Jan for the South African snakes *lacteus* and *dorsalis*, and the retention of Elapidae as the family name.

In another development Savitsky (1979 - a widely quoted, but as yet unpublished doctoral thesis) questioned the affinities of New World coral snakes *(Micrurus)* with other proteroglyphs, considering them more closely related to South American elapomorphines. This remains a disputed relationship, and the proposal has not been followed in Golay's checklist, and is unsupported by recent immunological (Cadle and Sarich 1981) or morphological (McCartney 1985) studies. Its acceptance, and/or the transfer of the Australian terrestrial proteroglyphs back into the Elapidae, would require radical changes in the content and arrangement of this checklist.

The book is printed on good quality glossy paper, with a soft cover illustrated with a rather etiolated mamba *(Dendroaspis viridis).* Ninety-six pages of text break down into: Titles and Acknowledgments, 4 pp.; Preface, 2 pp.; Figs. (scutellation), 3 pp.; Generic List, 1 pp.; Generic Key, 2 pp.; Checklist and Key to Species, 54 pp.; Bibliography, 19 pp.; Journal Abbreviations, 39 pp.; and Index, 8 pp. I could find no typographical errors in the sections I am most familiar with (i.e., African genera). Keys to all recognised taxa (including races) are present, although these are somewhat abbreviated and may cause confusion with anomolous or intergrade specimens, e.g., many Namibian coral snakes *(Aspidelaps lubricus infuscatus)* lack distinct body bands and would be confused with the northern race *(A. l. cowelsi)* using Golay's key. Overall, this **Checklist** is very thorough, up-to-date (as of 1984), and well produced.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1985

Student member	$17.00*	Sustaining member	$35.00
Regular member	$22.00*	Contributing member	$50.00
Institutional	$40.00		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

9TH ANNUAL REGIONAL HERPETOLOGICAL SOCIETIES CONFERENCE

The Ninth Annual Conference of the Regional Herpetological Societies sponsored by the SSAR will be held on the afternoon of Wednesday, 7 August 1985 with the joint meeting of the SSAR and HL at the University of South Florida in Tampa, Florida. The title of the conference is "Methods to Enhance the Regional Herpetological Society." The program will include the following presentations:

John Simmons (Kansas Herpetological Society) and Martin Rosenberg (Northern Ohio Association of Herpetologists) will present techniques used to enhance the KHS and NOAH through the publication of newsletters.

Thomas Vermersch (Greater San Antonio Herpetological Society) will discuss the procedures for putting on a mall show.

Joseph Collins (Kansas Herpetological Society) will discuss how auctions can be used to enhance the regional society.

Dave Barker (Texas Herpetological Society) will discuss the problems of organizing an annual conference.

Peter Meylan (All Florida Herpetological Conference) will give the rationale for the Florida conference and discuss ways in which the herpetologists of Florida might be better served by an enlarged or different system than presently practiced.

John Murphy (Chicago Herpetological Society) will present the CHS philosophy of field trips and how field trips have enhanced the society.

Terry Hibbitts (Texas Herpetological Society) will present the rationale of the THS's forty years of annual field trips and how they have enhanced the society.

There will also be tables available for regional societies to distribute information about their society. Each society should provide approximately 100 brochures about their society to be distributed at the conference. The brochure should include purpose, history, activities, membership categories, dues, and contact person for additional information.

Additional information on the conference may be obtained from:

Terry Hibbitts
Chair Regional Society Liaison
309 S. 4th Street
Wylie, Texas 75098 U.S.A. ●

LETTER TO THE EDITOR

EDITOR:

I was disappointed to learn that the SSAR and the HL was offering (selling at $11.00 a plate) "alligator and turtle" at this year's combined meeting for the closing night dinner in Tampa, Florida. It seems ironic to me that societies concerned with the study and preservation of herpetofauna would sanction such an activity.

I noticed that the description in this announcement stated that both these species are "legal game animals in Florida." It should be noted that not always is an act ethically or philosophically proper simply because it is legal.

Please do not misunderstand . . . I fully support placing a commercial value on and/or the take of wildlife when such a value or take *benefits* the species involved, such as some legal crocodile farming, Alfrican wildlife conservation programs, etc.

In my profession, working for the government in the field of wildlife protection, I have the opportunity to observe thousands of commercial shipments of wildlife and wildlife products. At least once a week large crates containing hundreds of wild caught and "farmed" adult turtles arrive at the San Francisco International Airport destined for various food markets. Usually these shipments consist of live and semi-live *Trionyx, Pseudemys* and *Graptemys* which are carelessly packed on top of each other three to four feet in depth. Turtles that can survive the packing and shipping traumas (usually the animals on top) are often boiled to death at the market place or in the hands of the final consumer. Oftentimes these consignments are left for days at the airport of destination before they are picked up by the wholesaler or retailer. This activity tends to make me lose my appetite rather than enhance it . . .

Since societies such as the SSAR and HL can affect the attitudes of the scientific community as well as the general public, I feel it is extremely important that careful consideration be given on which activities they "place their stamp of approval."

NEWSNOTES

NIXON GRIFFIS FUND FOR ZOOLOGICAL RESEARCH

The Nixon Griffis Fund for Zoological Research established in 1984 by New York Zoological Society Trustee Nixon Griffis, announced its first seven grant recipients on 7 March 1985. Grants are available to members of the zoo and aquarium community. Recipients may be curators, keepers, veterinarians, or research and consulting biologists.

One of the seven grants awarded in March 1985 was in the area of herpetology. Dr. Dale Marcellini, National Zoological Park, received an award for "A study of the ecology, behavior, and captive husbandry of the New Zealand Gecko, *Naultinus elegans*."

Grants, not to exceed $3000, are awarded semi-annually. Closing dates for grant requests are 1 January and 1 July each year.

For further information write to the Nixon Griffis Fund for Zoological Research, c/o New York Zoological Society, 185th Street and Southern Boulevard, Bronx, New York 10460, U.S.A. ●

CHUCKWALLA RESEARCH EXPEDITION

The Zoo and Aquarium Travel Association is planning a series of expeditions to San Esteban Island in the Sea of Cortez to study the endangered San Esteban Island chuckwalla. Staff from the Arizona-Sonora Desert Museum and ZATA will lead this zoo research program which will gather data about the behavior, blood chemistry, natural diseases, weights and measurements of this lizard to use and apply in the care and breeding of captive populations. Any individual interested in becoming a member of this research expedition should contact:

Birmingham, Alabama 35216, U.S.A. ●

PROCEEDINGS OF THE 2ND EUROPEAN CHELONIAN SYMPOSIUM, OXFORD 1981

The 2nd European Chelonian Symposium was held in the Department of Zoology, University of Oxford, 3-4 October 1981 and was

integrated with the first two days of the International Herpetological Congress (3-9 October 1981) organized by J. Coborn. Edited by M.R.K. Lambert (Chairman, British Herpetological Society, London), the Proceedings have now been published in two parts.

PROCEEDINGS A— Published in *Amphibia-Reptilia* 5(1):1-80, March 1984, the Journal of the Societas Europaea Herpetologica. Contains papers on the status, conservation, breeding, and ecology of tortoises, including *Testudo hermanni robertmertensi, T. h. hermanni, Chersina angulata,* and *Psammobates geometricus.*

PROCEEDINGS B— Published in *Testudo* 2(2):1-32, 1983, the journal of the British Chelonia Group, Bristol. Contains papers on *Testudo hermanni robertmertensi, Testudo h. hermanni, Mauremys caspica leprosa,* reviews of films concerning the tortoise trade, and a paper on the R.S.P.C.A. and the tortoise trade.

ORDERS— Proceedings A may be ordered through any bookseller or direct from the publisher of Amphibia-Reptilia: E. J. Brill, Postbus 9000, 2300 PA Leiden, The Netherlands. Back numbers may only be available in complete volumes (120 Dutch guilders + 16 guilders postage and packing). Proceedings B are available at £1.50 ($3.50) from Mr. G. N. Wallace, Librarian, British Chelonia Group, 36A Wetlands Lane, Portishead, Bristol BS20 8NF, U.K. Cheques, postal orders and international money orders should be made payable to British Chelonia Group. ●

PHOTOGRAPHS NEEDED FOR VENOMOUS SNAKE BOOK

Work is presently underway on a manual of the venomous snakes of Latin America (Mexico southward). Assistance from the herpetological community is urgently needed in the form of color transparencies (slides) and negatives (color and black-and-white) depicting venomous snakes of the region. For further information please contact immediately: **J. A. Campbell** or **W. W. Lamar,** Department of Biology, The University of Texas at Arlington, Box 19498, Arlington, Texas 76019, U.S.A.

IN MEMORIAM

On October 14, 1983 Kenneth Ichiro Miyata died in a fishing accident in Montana. He was then thirty-two years old, just at the beginning of multiple careers. He was already and simultaneously an author whose first book was about to come out, a nature photographer whose pictures were very publishable, a world class fly fisherman, and a well-known and respected herpetologist, collaborating with the top men in the field. He had just begun a job with Nature Conservancy International.

Born in Los Angeles, Ken was sansei, third-generation Japanese American. He was raised in Covina, a suburb of Los Angeles, learning about wildlife and fishing in the mountains just north of that urban sprawl. Even before kindergarten he was sketching snakes and lizards. At 10 he was taught fly casting by his grandfather in the West Fork of the San Gabriel River. At 12 he was tieing his own trout flies. By 18 he was earning a living selling them.

He graduated summa cum laude from Berkeley in the Department of Conservation, having done salamander mapping for David Wake. With excellent recommendations, he entered Harvard. I met him first in the Miami Airport when he joined my group that was about to visit Puerto Rico, the Dominican Republic, Venezuela, Colombia, Panama and Jamaica. He was never again long out of touch with tropical America, making more than 20 trips and adding Costa Rica, Ecuador, and Peru as well as the Galapagos to the areas that he knew. Ecuador he came to know best, becoming an expert on its herpetofauna. Between 1976 and 1982 most of his trips were Earthwatch-supported: he was collecting data for his thesis and at the same time proving to be a very effective recruiter for field biology. His thesis, for which he was given a Ph.D. in 1980, was one of the thickest ever produced at Harvard — but it was not padded. Its major chapter — on patterns and factors in diversity in world herpetofaunas —still to be published — will be important.

There was a period of uncertainty after the degree; some called it drifting. Ken had the skills of a scientist, but he did not want to be an academic. He applied, with reservations, for the vacant Curatorship of Herpetology at the San Diego Natural History Society. Although he was one of the "short list," his failure to commit himself was recognized. He was not chosen. He then obtained a Post-doctoral Fellowship in the Department of Herpetology at the National Museum of Natural History and was finishing his year of study when he was hired by Nature Conservancy. He had been there for only a few months and had gone on a short vacation — a condition of his acceptance of the job — to go to a fishing spot he had often visited, when, quite alone, he drowned after taking a picture.

He was never inactive either before or after his degree. His period of uncertainty was a reflection of his unwillingness to give up any of his careers. While doing his thesis, and after, he was trout-fishing, writing or planning the writing of herpetological articles and formal papers, fishing articles, and the book on "Tropical Nature" posthumously published by Scribners, and photographing all the while. He was superb at all of these, but until he was hired by Nature Conservancy, he did not have any secure way to make a living. His "hobbies" were expensive, his love of them compulsive, his pursuit of Academia at best desultory. He was attempting something that in the crass world around him was very difficult.

He carried his science into the sport of fishing, taking notes on each fish for his microcomputer, as though he were about to invent a science of fly-fishing. (Those who are afficionados of the sport would say he was well on his way to doing so.) He brought to the observation and collection of frogs, lizards and snakes the joy, the patience, the field knowledge, the hands-on knowledge that were also his in fishing and photography. He brought to his writing as well a sense of the joy that he felt in the field but also the discipline and accuracy that made him very genuinely a scientist in every respect except the economic — and that tide was turning at the time of his death. He was already at his young age a conspicuous, an extraordinary success.

Only when Ken died did I discover how little I knew about him, about his multiple lives. I then found I was not alone. Yet while Ken was quiet, he was not at all secretive. He put no effort into the separation of his several lives. He entered each fully, combined more than one when he could. Mark Skinner tells of him that "he carried his camera whenever he was outside so that up to his thighs in water, he had this expensive Nikon in a back pouch. It was as if he couldn't bear to be doing only one of the things he loved." His several lives did touch — wherever and whenever it was natural for them to do so. He just lived the lives he wanted to — much more than most of us ever do. (There was also the corresponding pattern — inevitably — of reluctance to do those things he did not enjoy.)

It is true tragedy when death comes to the young, before whom the world is just opening. In Ken's case the loss is not only to his family — an extended family with roots all over the United States and in Japan as well —nor to me nor his other friends, often totally unknown to each other, but also to each of the several fields in which he had already made a stellar place. Great things were expected of him, and we who knew him knew that in each area the expectations would have been realized.

It is the personality that we most remember. Many adjectives could and have been used regarding him, all with some special sense. Honest — in the most rigorous sense; honest about himself, self-knowing. And with the other face of honesty: intolerance of fraud, fuss and pretense. Ambitious in the most important sense — having the wish and the will to be first rate. Gentle — in the sense of a natural friendliness that is the reverse of demanding, that gives without requiring return.

My acquaintance with parts of Ken's life and with many of his friends and family really began after his death. I had hoped with the aid of the memories of his friends to pull together an adequate but very personal portrait of a friend whom I knew too briefly and incompletely. That portrait will not be written; the task has defeated me. Ken deserves a better memorial than I am to provide. However, there are other memorials possible. Three memorials are already in place:

1. ***HIS BOOK.*** Coauthored with Adrian Forsyth, the book was written with separate chapters by each author. Ken's chapters bear his distinctive stamp. Those who wish to know him better than they did and those who never knew him will relish "Tropical Nature" by Forsyth and Miyata (Scribner Book Company). It is a book that should be supplemen-

tary reading for any course in ecology, particularly any that mention or emphasize tropical ecology.

2. ***AN ARCHIVE OF MEMORABILIA,*** especially reminiscences of Ken, that is accumulating at the MCZ, and to be added to the formal archives of the Museum. In addition the Miyata family has deposited Ken's field notebooks — superbly detailed accounts of each of his field trips — in the Department of Herpetology MCZ.

I invite all those who knew Ken to send slides, reminiscences or anecdotes to the MCZ for inclusion in Ken's personal archives. These reminiscences will be available for inspection only with the consent of the sender. The notebooks and herpetological slides will be accessible to any serious researcher — as Ken would certainly have wished.

3. ***A MEMORIAL FUND*** has been established at Harvard University, the income to be used for graduate or undergraduate field research in herpetology. Gifts to this fund are solicited.

ERNEST E. WILLIAMS
Museum of Comparative Zoology
Harvard University
Cambridge, Massachusetts 02138, U.S.A. ●

THE KENNETH MIYATA FUND IN HERPETOLOGY

Named as a memorial to Kenneth Miyata, herpetologist, fisherman and writer, who died in a fishing accident in late 1983, this fund is restricted to support of graduate or undergraduate field research in herpetology or, in the event of no suitable project during any year, additions to the herpetological collections of the Museum of Comparative Zoology, or other uses relevant to the advance of herpetology. The fund is to be administered by a committee chaired by the Curator of Herpetology and including two other members to be appointed by the Director of the Museum of Comparative Zoology.

Gifts to the fund should be sent to the Museum of Comparative Zoology, Cambridge, Massachusetts 02138, U.S.A. (Attention either Ernest E. Williams or James J. McCarthy, Director). They will be acknowledged by the Recording Secretary, Harvard University and by Dr. McCarthy. ●

SOCIETIES

ANNOUNCING THE FORMATION OF A.P.E.A.

We are pleased to announce the formation of the Associazione Piemontese Erpetologia e Acquariologia. After several meetings held in 1983 by a small group of enthusiasts from the Piedmont area, in mid-1984 A.P.E.A. was founded, an official constitution and by-laws were adopted, and a precise program was scheduled for 1985.

At present, A.P.E.A. is the only Italian herpetological and ichthyological association, with a membership of about 70, with local and out-of-area membership.

Meetings are held every second Friday of each month (except July and August) beginning at 7:00 p.m. in Turin 7th District Hall. A bimonthly newsletter is distributed to all members and a Bulletin will start in late 1985, following collaboration with other acquariological societies. It will contain articles and original papers on all aspects of herpetology and ichthyology, translations of articles, and book reviews, all illustrated with b/w photos and drawings. We hope to have at least two issues of our Bulletin in 1986, after the formation of a federation of Italian Societies expected for October 1985. Manuscripts, notes etc. for the newsletter and Bulletin are invited from members and non-members.

Organized field trips and tours are held regularly. Various other activities such as live animal displays, conferences, educational and research programs have already been scheduled for 1985, in collaboration with other naturalistic organizations, museums and regional ecology departments.

Current officers for 1985 are:
President: Ettore R. Peyrot
Vice-President: Franco Andreone
Secretary-Treasurer: Luciano Mariotto
Councillors: Roberto Saracco
Nicola Mancuso

We are now looking forward to liaison with other societies, worldwide, for exchange of publications and information. All persons, amateur or professional, interested in fishes, amphibians and reptiles are invited to join us. 1985 dues rates are £ it. 15,000 for regular members, £ it. 25,000 foreign and £ it. 30,000 institutions.

For further information write to:

NORTH TEXAS HERPETOLOGICAL SOCIETY

The North Texas Herpetological Society was conceived by four individuals in September of 1982. The first meeting was held 24 October 1982 in the Fort Worth Museum of Science and History, where the Society continues to meet the second Sunday of each month at 2:30 PM.

The purpose of the NTHS is to "promote, stimulate and perpetuate the knowledge of reptiles and amphibians; to encourage continued education of members on all aspects of Herpetology; to promote the preservation of all reptiles and amphibians; and to contribute to the advancement of Herpetology."

The Society is presently working on a slide presentation entitled "A Pictorial Guide to the Reptiles and Amphibians of Dallas and Tarrant Counties, Texas." Members have presented shopping mall exhibits, local cable TV shows, lectures to public school groups, and have aided the City of Fort Worth in rewriting their Animal Control Ordinance. The Society also publishes a monthly newsletter.

Membership rates:

Regular Membership	$ 8.00/year
Family	$10.00/year
Subscribing	$ 6.00/year

For information contact:
North Texas Herpetological Society
c/o Fort Worth Museum of Science and History

FEATURES

DISTRIBUTION OF THE EASTERN INDIGO SNAKE, *Drymarchon corais couperi*, IN FLORIDA

Although earlier workers had reported the eastern indigo snake *(Drymarchon corais couperi)* to range more or less continuously from South Carolina to southern Louisiana (e.g. Schmidt and Davis 1941; Smith 1941), Neill (1954) concluded that there was a distributional hiatus in west Florida between Okaloosa and Gulf counties. Further restricting the distribution, Conant (1958) reported the snake to occur in two major separate population centers, peninsular Florida and southeastern Georgia, and in three smaller western disjunct populations, one near Mobile, Alabama, another extending from Okaloosa County, Florida into Covington County, Alabama and a third centered in the lower Apalachicola region of Florida. Subsequent workers have attempted to refine our knowledge of *Drymarchon* distribution, with the result that the ranges of the separate population units have been enlarged somewhat and in some cases coalesced (Conant 1975; Mount 1975; Kochman 1978; Ashton and Ashton 1981), though typically without discussion or documentation. Diemer and Speake (1983) have recently reported the results of an intensive investigation of the distribution of the eastern indigo snake in Georgia. This paper documents the distribution of this snake in Florida.

The preserved collections of the Florida State Museum (UF), Tall Timbers Biological Station (TT), and Archbold Biological Station were personally examined. Records from the following collections were provided by personnel of the respective institutions: Academy of Natural Sciences, American Museum of Natural History, California Academy of Sciences, Carnegie Museum of Natural History, Charleston Museum, Cornell University, Duke University (DU), Field Museum of Natural History, Illinois Natural History Survey, Indiana State University, Louisiana State University, Museum of Comparative Zoology, Museum of Zoology of NE Louisiana University (NELU), National Museum of Natural History (USNM), Natural History Museum of Los Angeles County, Natural History Society of Maryland, North Carolina State Museum of Natural History, Peabody Museum of Natural History, San Diego Natural History Museum, Savannah Science Museum, Southern Illinois University, Texas Natural History Collection (TNHC), University of Central Florida, University of Colorado (UCM), University of Georgia Museum of Natural History, University of Illinois Museum of Natural History, University of Kansas Museum of Natural History, University of Michigan Museum of Zoology, University of Minnesota Museum of Natural History, University of Nebraska State Museum (UNSM), University of New Mexico, University of South Alabama, University of South Florida, University of Southwest Louisiana (USWL), College of William and Mary (CWM). Records from the University of Miami Reference Collection were provided by J. Kushlan.

Museum records were initially compiled in early 1981. Records for the Florida State Museum have been updated and are current to January 1984. In order to supplement museum records, biologists and other individuals familiar with the indigo snake were interviewed. Although this interview process provided records statewide, a particular effort was made to locate individuals with knowledge of indigo snakes in the panhandle and northern peninsula. For a more detailed treatment of the distribution of the indigo snake in extreme southern Florida see Steiner et al. (1983).

Complete lists of the museum and interview records included here have been deposited in the libraries of the Herpetology Section, Florida State Museum and the Division of Amphibians and Reptiles, National Museum of Natural History.

Of 39 institutions surveyed, 7 (DU, NELU, TNHC, UCM, UNSM, USWL, CWM) had no Florida *Drymarchon* in their collections. The remaining 32 institutions reported a total of 236 Florida *Drymarchon*, of which 197 specimen localities could be mapped with reasonable accuracy. Museum specimens are available from 44 counties.

Another 355 records were derived from interviews with 95 individuals judged to be reliable sources. Sighting records were provided from 63 counties.

Altogether 552 occurrence records were mapped (Figure 1). These include records for all Florida Counties except Gulf, Lafayette and Union.

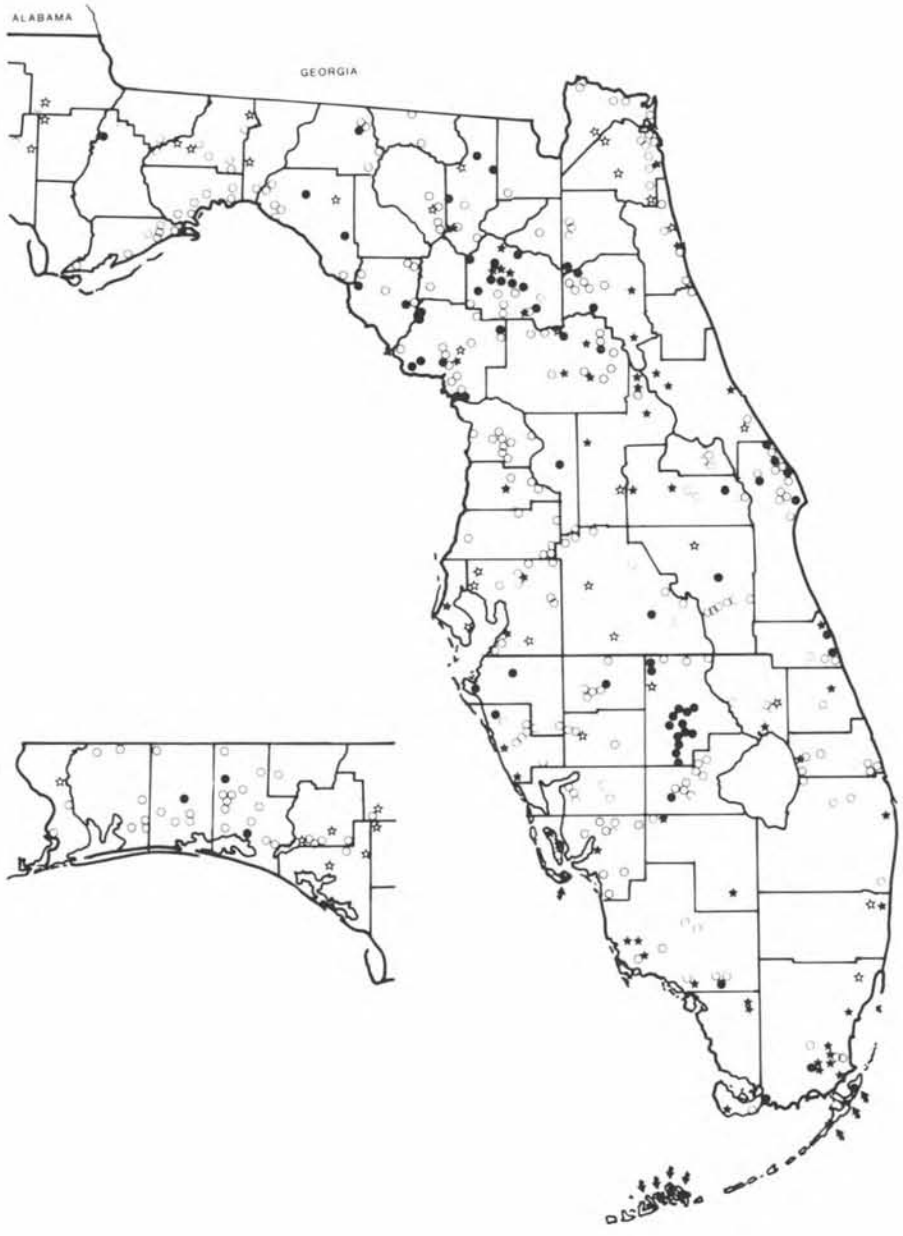

Figure 1. Florida distribution of the eastern indigo snake. Circles: recent records. Stars: records prior to 1970. Solid symbols: museum specimens. Open symbols: sighting records. Individual symbols may include more than one locality.

Although sandhills are a dominant feature of the west Florida landscape, the three herptiles which people most often associate with Florida sandhill habitats, the indigo snake, the gopher tortoise *(Gopherus polyphemus)* and the gopher frog *(Rana areolata),* have each at one time been suggested to have a distributional hiatus in west Florida (Goin and Netting 1940; Neill 1954). Subsequent workers have concluded that the gopher tortoise (Neill 1954; Auffenberg and Franz 1978) and the gopher frog (Mount 1975; Altig and Lohoefener 1983) are more or less continuously distributed through west Florida and extreme southern Alabama. However, the perception has persisted that the indigo snake occurs in Alabama and panhandle Florida only in two or three widely disjunct populations (McCranie 1980; U.S. Fish and Wildlife Service 1982). This impression may derive in part from the fact that prior to 1973 there were no museum specimens available from Florida west of the Suwannee River. [Note - USNM 10565, collected in 1881 and presumably the basis for the Santa Rosa County record mapped by Ashton and Ashton (1981), proved upon examination to be a black racer *(Coluber constrictor)* (R. McDiarmid, pers. comm.)]. Since 1973, ten *Drymarchon* have become available from Okaloosa (UF 54664), Walton (TT 679, UF 54665), Liberty (TT 731), Franklin (TT 704), Madison (UF 47362), Taylor (UF 51206, UF 52583) and Dixie (UF 55135, UF 55136) counties. From these specimens and the additional records provided here it is clear that the indigo snake is distributed widely, though not necessarily commonly, throughout Florida, including the panhandle.

Diemer and Speake (1983) have recently shown the indigo snake to be more widely distributed in Georgia than previously thought, and it is here demonstrated that it is continuously distributed throughout Florida. In view of the several recent Florida records within a few miles of the Alabama border, it seems likely that research would show *Drymarchon* to still occur naturally in that state.

The cumulative nature of museum records perhaps makes them less reliable than sighting records as an indicator of current distribution. The interview process, with its emphasis on active biologists, tended to produce a preponderance of recent records. Whereas only 34% of museum specimens have been collected since 1970, 86% of the sighting records have occurred since 1970. Altogether, 387 (70%) of the 552 records reported here have occurred since 1970. Disallowing all records prior to 1970, it is apparent that *Drymarchon* still occurs widely throughout Florida.

ACKNOWLEDGMENTS

I gratefully acknowledge the curators and other personnel of the museums surveyed and the many individuals who provided sighting records and salvaged specimens. Without their generous assistance this work would not have been possible.

L. T. Stock prepared the map, T. L. Crown typed the manuscript and C. L. Abercrombie provided constructive criticism of the manuscript.

This is a contribution of the Federal Endangered Species Program, Florida Endangered Species Project E-1 and was financed in part with grant-in-aid funds under Section 6 of the Endangered Species Act of 1973 (PL 93-205).

CORRECTION OF THE NORTHERNMOST LEATHERBACK NESTING ON THE U.S. ATLANTIC COAST

Nichols and Du Toit (1983) reported a nesting emergence of a leatherback *(Dermochelys coriacea)* at Beverly Beach, Flagler Co., FL, to be "the furthest north on the U.S. Atlantic coast that a leatherback nesting has been definitely documented." This is incorrect. Ruckdeschel, Ellis, and Shoop (1982) documented nestings in 1981 on Cumberland and Blackbeard Islands, GA. Voucher specimens (embryos and dead hatchlings) from both nestings were deposited in the Savannah Science Museum Herpetology Collection: SSM 9884 (Cumberland Is. series) and SSM 10147 (Blackbeard Is. series).

Thus, the Blackbeard Is., GA, record is actually the leatherback's northernmost confirmed nesting on the U.S. Atlantic coast.

A REVIEW OF SQUAMATA OVIPOSITING IN ANT AND TERMITE NESTS

There are widely disseminated reports of lizards, snakes and amphisbaenians ovipositing in the nests of termites and ants. This important, but neglected, aspect of squamate brood provision is reviewed here for the first time. The full names of all the reptile species mentioned in the text, together with the author and date, are presented in Table 1.

ANT NESTS

Tschudi (1867) appears to be the earliest report of Squamata depositing eggs in ant nests: he mentions an egg clutch of *Coluber* (i.e. *Chironius*) *bicarinatus* in the upper "Panellen" (we are unsure as to what area of the nest this refers) of ant nests ("Tanajuras") in Brazil. He also notes that *Amphisbaena flavescens* (=*A. alba*) and *A. fuliginosa* inhabit similar regions of the same ant nests and there lay eggs but it is not clear from the original text which of the two amphisbaenians was responsible for the eggs. These observations (also cited in Vaz-Ferreira et al.

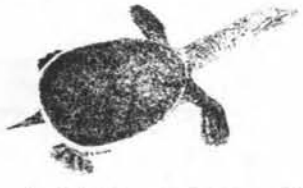
1970) have not been confirmed in any subsequent publication. Boulenger (1885b) comments upon two eggs of an amphisbaenian *(Anops kingii)* recovered by Ihering from "an ant nest" (species unknown) in Rio Grande do Sul, Brazil, and Goeldi (1897) provides evidence that *Lepidosternon* (= *Leposternon*) *microcephalum* regularly lays its eggs in ant hills of the genus *Camponotus* in Rio de Janeiro.

Smith (1935) mentions that the eggs of *Varanus monitor* (= *V. bengalensis*) are "deposited in a hole or ant-heap." This species is well known for its habit of excavating holes in which to lay eggs (Deraniyagala 1958; Misra 1960) and it may be that they do occasionally dig into ants' nests, possibly by accident: the available evidence does not suggest that there is a regular association between *V. bengalensis* and ants. This is the only species for which there is an egg-laying association with both ants and termites. Deraniyagala (1953) states that *Varanus cepedianus cepedianus* (= *V. bengalensis*) in Sri Lanka deposits its eggs "either in the ground or in a decaying log or a termite hillock which ensures daily warmth by the sun and a moderate degree of moisture."

Vaz Ferreira et al. (1970, 1973) excavated 697 nests of 5 species of leaf-cutter ant (all of the genus *Acromyrmex*) in Uruguay and found eggs, eggshells or, more rarely, hatchlings of 8 species of snake and one species of lizard in 103 nests (indicated by an asterisk in Table 1). Two snake species, *Philodryas patagoniensis* and *Liohis obtusus* accounted for the vast majority of findings, at least 146 egg clutches being recovered from 83 nests (mostly nests of *A. lobicornis*). The remaining 7 Squamata, infrequently encountered, were each represented by between 1 and 5 clutches. Eggs were mostly located in the central fungus chamber of ant nests, although those of *Liophis obtusus* also occurred in secondary fungus chambers and in roof passages close to the central chamber. Eggs of *Elapomorphus bilineatus*, found on one occasion, were in connecting passages close to the central chamber and egg clutches of *Teius teyou* were frequently in peripheral passageways, away from the fungus chambers. A point of particular interest is worth mentioning: a single nest contained a total of 200 eggs and eggshells comprising 17 clutches, 16 of *P. patagoniensis* and one of *L. obtusus*. In healthy fungus gardens eggs were of normal shape and colour but in abandoned or dying gardens they were frequently shrivelled and discoloured and contained proportionately more dead embryos. Clearly the conditions provided for egg incubation by normal nests are necessary for successful development. However Gudynas (1979) has found a clutch of eggs from the teiid *Teius teyou* under a rock but he points out that individuals laying their eggs in ant hills may be afforded some selective advantage.

Weber (1972) has found snake eggs (species unknown) on several occasions in the fungus gardens of *Atta colombica tonsipes* (= *A. colombica* Guérin, 1845) in Panama. In Trinidad Emsley (1977) mentions that the eggs of another South American snake, *Pseudoboa neuweidii*, have been found in the nests of bachac ants (*Atta* sp., *Acromyrmex* sp.) and Riley & Winch (1985) also report the eggs of two other colubrids in the nests of these leaf-cutter ants; *Leptodeira annulata* in *Acromyrmex octospinosus* nests and *Tripanurgos compressus* in an *Atta cephalotes* nest.

TERMITARIA



Schomburgk (1848) provided the first account of a lizard using termite nests for brood provision when he described the tegu *"Podinema tequixin"* (undoubtedly *Tupinambis nigropunctatus*, following Boulenger (1885a) in our use of species names in the genus *Tupinambis)* laying 50-60 eggs in tree termite nests in Guiana. Further accounts of the eggs of this species in termitaria, provided by Kappler (1854), Goeldi (1897), Hagmann (1906), Reese (1922) and Beebe (1945), serve to confirm an obligate association: it is not known to lay eggs in other situations. The termite species in one instance reported by Beebe (1945) was *Nasutitermes ephratae* (Holmgren 1910). Newly hatched lizards apparently claw their way through the nest to effect escape, a process which may be facilitated when nests are softened by rain (Everard and Boos 1975).

Goeldi (1897) states that *Tupinambis teguixin* also prefers to lay its eggs in termite nests but he gives no evidence. *T. tequixin* is well known to lay eggs under vegetation and in holes (Schouten 1929; Serié 1932). Goeldi (1902) repeats his claim, stating that the phenomenon had been reported by Schomburgk and confirmed by his (Goeldi's) eldest son. We know that Schomburgk's observations relate to *T. nigropunctatus*. However, Goeldi's son's observations were said to have been made in the Serra dos Orgaos which is near Rio de Janeiro, within the range of *T. tequixin* and well outside the range of *T. nigropunctatus*.

Gosse (1850), in a general account of *Typhlops lumbricalis* (Jamaican populations of which are now assigned to the species *T. jamaicensis*) stated simply that "the egg is laid in the earthy nests of termites." Later Gosse (1851) relates finding a single egg of this species in a deserted termite nest. Gosse's observations appear to have been either overlooked or ignored by subsequent workers. For example, Grant (1940) states "The writer has heard much of their occurrence in termite nests, but has not found any in hundreds of nests he has examined." However, recent confirmation of the association of this species with termite nests has been provided by Dr. Garth Underwood (pers. comm.) when, in July 1957, a collector in Jamaica brought him a clutch of four *T. jamaicensis* eggs that had been found in a termite nest: whether this nest was active or deserted is not known.

Goeldi (1897) states that it is a fact beyond doubt that *Dracaena guianensis* lays its eggs in termitaria. However, he admits that practically nothing is known of the natural history of this species and seems to have based his claim on the fact that two species of tree termites make their nests in areas inhabited by this lizard. As far as we know, the eggs of this species are still unknown in the wild.

Hagmann (1906) describes clutches of 2-3 eggs of the gecko *Gonatodes humeralis* in termitaria. However, there are many observations of this particular species laying beneath bark and in hollows at the bases of trees (Hoogmoed 1973). Hoogmoed states that *G. humeralis* lays a single egg and although females often contain two eggs they are always at different stages of development and the first is laid long before the second. Hagmann's clutches were clearly therefore not true clutches: that he observed the phenomenon in several nests suggests that its

CHECKLIST OF TURTLES OF THE WORLD
by DR. JOHN IVERSON
HERPETOLOGICAL CIRCULAR NO. 14 Available in September 1985

A comprehensive guide to the common names and scientific nomenclature for the turtles of the World

Price to SSAR members until September 1, 1985.....$2.00 postpaid

? Awaits confirmation
1 Probable obligate association, many records of oviposition in ant or termite nests, not known to nest elsewhere
2 Possible obligate association, relatively few records of oviposition, but not known to nest elsewhere
3 Facultative association, known to lay eggs in other sites
* Reported in Vaz-Ferreira et al. 1970, 1973

occurrence may be quite normal. These observations are confirmed by Beebe (1944) who noted that these geckos use the outer, semi-deserted parts of the nest in order to avoid being walled in. According to Hoogmoed (1973:83), Beebe (1944) had misidentified the geckos as *Gonatodes annularis* Boulenger, 1887; they were, in reality, *G. humeralis*.

The habit of using termitaria for brood provision seems to be well established in monitor lizards. The association was first reported by Theobald (1868) although in that case the termite nests were said to be deserted and it is not clear to us whether the species involved was *Varanus flavescens* (Hardwicke and Gray 1827) or *V. bengalensis*. Cowles (1928), FitzSimons (1932) and Branch and Erasmus (1982) report *Varanus niloticus* laying its eggs in termitaria: we have been unable to find any reference to its laying in other situations. Also Bustard (1970) states "that a number of large *Varanus* including the Australian lace and sand monitors sometimes use termite mounds as incubators for their eggs" and Cogger (1967) reports that *V. varius* and *V. gouldii* lay eggs in other situations. But the association between Rosenberg's sand monitor *Varanus gouldii rosenbergi* (actually a full species according to Storr, 1980) and termites might be more specific than the above implies. King and Green (1979) for example, record two clutches of 10 and 12 eggs of this species in termite mounds and we can find no record of its laying elsewhere.

Kopstein (1929) describes *Dipsadomorphus* (now *Boiga*) *jaspidea* eggs hatching in the nest of the termite *Lacessititermes sordidus* (Haviland 1898) and later (Kopstein 1932) he reports Dr. Kalshoven finding two *Sphenomorphus sanctus* eggs in a *Nasutitermes matangensiformis* (Holmgren 1913) nest in Java. In summaries of the species of reptile known to oviposit in termitaria in Java, Kopstein (1935, 1938) adds *Boiga drapiezii* to the list, bringing the total to three.

Bogert (1940) reports the presence of an adult female, young and eggs of *Typhlops avakubae* (now considered a synonym of *T. caecus*) in a termite nest under a roof at Kassa, French Congo, and Loveridge (1942) describes a clutch of 6 eggs of *Boeadon* (=*Lamprophis*) *lineatus* (actually *fuliginosus*) found in a termitarium at Mushongero, Kenya. This species also lays its eggs in decaying vegetable matter, manure heaps, etc. (Broadley 1983).

A remarkable association between the gecko *Gehyra pilbara* and the nests of the termite *Eutermes* (now *Nasutitermes*) *triodiae* (Froggat 1897) is described by Mitchell (1965). This species is found only within termitaria - in numbers of up to an estimated thirty per nest - together with numerous gecko eggs, both fertile and infertile, and egg fragments. This lizard shares this habitat with, and is preyed upon by, the dwarf python *Liasis perthensis* Stull, 1932 (Mitchell 1965). L. A. Smith (pers. comm.) adds that of the four species of the *L. childreni* complex he proposes to recognise, only two utilize termitaria, but not, as far as is known, for egg incubation. He adds that some *Ramphotyphlops* and *Delma* also utilize ant nests but again it is not known if they use them as nest sites.

Pongsapipatana (1975) reports that another gecko *Peropus* (= *Gehyra*) *mutilatus* "lays its eggs in termite nests" although this ubiquitous species is also known to lay eggs beneath bark and in holes in the ground (Gibson-Hill 1950; Oliver and Shaw 1953).

DISCUSSION

The eggs of at least eight of the reptile species mentioned herein have been found in the nests of ants and termites sufficiently often (and never elsewhere) to indicate a probable obligate association; another dozen or so may eventually be included in this category as more information becomes available (Table 1). By contrast nine species are known to oviposit in other locations and apparently most only occasionally make use of ant or termite nests for brood provision (Table 1).

Reptiles that regularly utilize nests as incubators for eggs are afforded a number of obvious advantages. Most reptile eggs are highly sensitive to changes in humidity and most oviparous species deposit eggs in substrates or situations which provide high, and relatively constant, humidities. Such conditions are characteristic of the nests of termites and particularly of leaf-cutter ants. For example, Mitchell (1965) noted that the termite *Nasutitermes triodiae* maintain the internal humidity of the nests close to saturation by varying the pattern and extent of ventilation. Vaz-Ferreira et al. (1970) observed that the fungus gardens of *Acromyrmex* spp. rapidly disintegrate in nests that have been broken open (by predators) or when they are transferred to conditions of low humidity. They further observe that *Acromyrmex* nests offer the only humid environments during the hot dry summer in Uruguay.

Thermoregulation of the nest environment is a general capability of social insects (Wilson 1976). Termite nests, harbouring the obligate inquiline *Gehyra pilbara*, were found to be on average 5-11° C higher than the surrounding air (Mitchell 1965) and evidence was provided that such a relatively constant microclimate enabled geckos to sustain a long, continuous breeding period, combined with an uninterrupted growth cycle. Likewise, Vaz-Ferreira et al. (1970) recorded that fungus-chamber temperatures of *Acromyrmex* spp. nests were stable in the range 27-29° C despite fluctuations in the external temperature of 21-32° C. Clearly nests make excellent incubators and Bustard (1970), in a discussion of the use of termitaria for varanid brood provision, mentions another advantage in that they also afford a degree of safety from predation. Likewise Vaz-Ferreira et al. (1970) comment that *Acromyrmex* nests provide both a physical barrier and a biological defence against predation. This factor will become increasingly important in species with long incubation times. *Varanus rosenbergi* eggs, for example, require 6-7 months to incubate at about 27° C (King and Green 1979) and *V. niloticus* hatch after 9-10 months in termite nests (Cowles 1930).

Reptile eggs in soil or humus are also susceptible to microbial attack and this possibility may be obviated if incubatory inquilinism is employed. Leaf-cutter ants in particular, which cultivate pure fungus cultures (Weber 1957) are meticulous about the hygiene of their nests: alien fungal spores and other particulate contaminants are licked up and temporarily stored in an infrabuccal pocket to be later removed from the immediate environment of the fungus (Weber 1972). Ants devote much time to licking all the internal nest surfaces (Quinlan and Cherrett 1977) and about 30% of ants on the surface of the fungus garden are at any time involved in this activity (Quinlan and Cherrett 1978). The same attention is apparently given to reptile eggs sequestered within fungus gardens which are often used as supports for fungus cultures and consequently their surfaces are kept clear of adhering foreign material (Vaz-Ferreira et al. 1970).

The problem facing reptiles in gaining access to solidly constructed termitaria for the purposes of oviposition, and the subsequent escape of hatchlings, are likely to be considerable and may only be possible for small species (e.g. *Typhlops*) or for species equipped with sharp claws for digging (e.g. *Tupinambis* and *Varanus* spp.). For most snakes therefore, this particular habitat is precluded and the observations of Kopstein (1929, 1935, 1938) of two *Boiga* spp. eggs in termitaria are all the more intriguing. Cogger (1967) mentions several instances of adult monitors being disturbed at termite mounds when newly hatched young are found emerging. He suggests that the female digs a tunnel into the mound when young are hatching to aid their escape. Beebe (1944) highlights the problem in his observations of the gecko *Gonatodes annularis* (actually *G. humeralis*) where he discovered two eggs and a newly hatched but dead gecko which apparently was too weak to free itself when walled in.

Some interesting observations of the behaviour of snakes emerging from eggs maintained in laboratory colonies of *Acromyrmex* have been made by Vaz-Ferreira et al. (1970). Hatching takes several hours and is preceded by a leakage of amniotic fluid through a split in the egg membrane. The head of the snake remains within the ring of fluid which apparently protects it from initial attack by ants. Once liberated from the egg, hatchlings seek rapid escape from the fungus gardens and are sometimes bitten by ants.

ACKNOWLEDGMENTS

We are very grateful to the following: Dr. E. N. Arnold and Dr. C. J. McCarthy (both BMNH) who commented on the typescript; Mr. B. Bolton (BMNH) for advice on ant nomenclature; Dr. W. A. Sands (Tropical Development and Research Institute) for advice on termite nomenclature; Dr. G. L. Underwood (City of London Polytechnic) who discussed oviposition in Trinidad and Jamaican snakes; Mr. C. R. Vardy (BMNH) and Dr. K. S. Sattler (BMNH) who both gave valuable assistance in translating Spanish and German texts respectively; and Dr. M. S. Hoogmoed (Leiden) who provided a copy of Kappler 1854. The research of JR and JMW was supported by a NERC Grant No. GR3/5016.

REPTILE CAGES

Designed with your needs in mind.

Desirable features of Herp-Huts:

- Should never have to be replaced.
- Molded in one piece of durable fiberglass, no seams, all corners rounded.
- Smooth finish facilitates easy cleaning and sterilization.
- Top front ridge, ideal for clamping heat lamp, if desired.
- Two vented louvers per cage (standard), designed to prevent scratches to animals and entrance of flies. Side or top mount possible.
- Side mounted vent plates make top/bottom interchangeable, creating pitch alternatives.
- Sloping front for easy viewing.
- Special vertical ridges on either side of cages "A" & "B" minimize possibility of small snakes getting wedged or escaping.
- Design suitable for reptile houses, mobile reptile exhibits, and reserve cages.
- ★ **Newest Option:** Feature requested - Hingeable front door with or without 5 inch safety glass shield.
- Traditional sliding glass front accessibity.

A New Approach to an Old Concept

Herp - Huts currently available in four standard sizes and colors: Blue, Aqua, Beige, White

Pictured:

Cage A: 16¼" W X 7½" H X 6¼" D $35.00
Cage B: 22¼" W X 9¾" H X 11" D $45.00
Cage C: 30¾" W X 16" H X 17¾" D $90.00
Cage D: 42½" W X 19¾" H X 24" D $125.00

Current Prices w/out front glass
All orders F.O.B. Henderson, TX

TECHNIQUES

RETENTION OF FLIPPER TAGS ON HATCHLING SEA TURTLES

The inability of researchers to find a tag suitable for hatchling sea turtles has been mentioned repeatedly in the literature (Carr 1967*a*, 1967*b*; Hirth 1971; Hughes 1974; Carr et al. 1978; Mrosovsky 1978*b*, 1982, 1983; Rudloe 1979; Hendrickson and Hendrickson 1980). Body dimensions and weight increase substantially as a hatchling grows from a few centimeters long to an adult of 70 cm or more. This factor has been viewed as a major obstacle to devising a practical tag that will stay in place. Furthermore, an added demand on such a tag is the many years (10-60) that may be required for a turtle to reach adult size (Balazs 1979, 1982*b*; Limpus 1979; Limpus and Walters 1980; Mendonca 1981). A successful tag for hatchlings has considerable potential for answering important questions about survival rates, geographical dispersal, the "lost year" pelagic phase, early growth rates, and nesting site affinities. It would also help in evaluating hatchery and head-start projects attempting to replenish depleted turtle populations.

Existing published information on attempts to tag hatchlings with an external mechanical tag suggests that such a tag is "... soon either overgrown or popped off by the increasing thickness of the tissue it perforates" (Carr 1967*b*; see also Hirth 1971; Hughes 1974; Mrosovsky 1983). However, the details of the experimental evaluation leading to this conclusion have not been reported. Plastic tags have been used on the hind flipper (Carr 1967*b*) and carapace (Uchida 1973; Hughes 1974) of hatchlings released into the wild, but no recoveries have been reported, and shedding rates have apparently not been estimated through captive rearing. There is no specific mention in the literature of the use of metal tags on hatchlings. Metal flipper tags have been regularly used on adult sea turtles at nesting sites since the early 1950s.

Besides external mechanical tags, other marking techniques that have been tried on hatchlings include the internal implantation of small magnets (Carr 1967*b*) and stainless wire (Hughes 1974; Schwartz 1981), branding (Carr 1967*b*), tattooing (Carr 1967*b*; Balazs 1978), injection of europium (Shoop 1978) and autografts (Hendrickson and Hendrickson 1980). Some workers have also marked hatchlings by cutting away or notching marginal scutes (Bustard 1972, 1979; Hughes 1974; Limpus 1978). However, this technique has not resulted in reliable long-term recoveries. Furthermore, a potentially confusing situation has developed because hatchlings have been notched in many different research programs over the years. There are also inherent difficulties in distinguishing a notch-mark from a natural injury (Mrosovsky 1978*a*).

An externally applied tag, such as a flipper tag, has substantial advantages over other marking techniques if it remains in place. These tags are far more likely to be recognized as a tag by the person resighting the turtle. They also permit a specific message to be visibly inscribed (i.e., return address, identification number) so that resighting data can be communicated back to the tagger.

A recent study in Hawaii of the shedding rates of metal flipper tags on small sea turtles indicates that this method of marking hatchlings should be seriously reconsidered. This note presents the results of the study, along with a discussion of its implications and requirements for further tag evaluation.

METHODS

In September 1980, hatchling green turtles, *Chelonia mydas*, were collected from French Frigate Shoals in the Northwestern Hawaiian Islands for use in testing a "living-tag" marking system involving autografts of contrasting pigmented tissue (Hendrickson and Hendrickson 1980). The hatchlings ranged from 5 to 6 cm in straight carapace length (SCL). Small Monel* tags (style 4-1005, size 1) from the National Band and Tag Co. of Newport, Kentucky were attached to the last right marginal scute of each hatchling to identify individuals during the study. These tags measure 8 x 2.5 x 2.5 mm when applied. They have been commercially available for many years, being advertised for use on fingerling fish, small mammals, and birds.

At 1 month of age, when the turtles ranged from 7 to 10 cm SCL, the tags had to be removed from the carapace due to distorted growth and necrosis of surrounding tissue. Replacement tags of the same size were then attached by the author to the trailing edge of the right front flipper. At 6 months of age (15-19 cm SCL) the same size tag was also applied to the left front flipper of each turtle.

Captive rearing of most of the turtles used for the living-tag study was completed at 12 months. The results of this work are reported elsewhere (see Hendrickson and Hendrickson 1981, 1983). The 174 surviving turtles averaged 23 cm SCL (range 16-30 cm) and 2.6 kg (range 0.7-5.2 kg). Each turtle was examined for the retention of flipper tags. At the same time, a larger Inconel® tag (size 681) was attached to a front flipper. Shortly thereafter, 169 of the turtles were released into the wild at several locations throughout the Hawaiian Islands.

RESULTS

Of the 174 yearling turtles, 147 (84.5%) still had both small flipper tags. One tag was missing from 26 (14.9%) turtles, and only a single turtle (0.6%) had lost both tags. Some tags were slightly corroded, but nearly all were still securely attached with little evidence of being overgrown or sloughing off (Fig. 1). Many tags had, however, rotated so that the long axis was perpendicular, instead of parallel, to the flipper's trailing edge. Of the 26 that lost 1 tag, 18 were from the right flipper applied at 1 month of age, and 8 from the left flipper applied at 6 months.

Five turtles were retained in captivity for continued rearing; four of these had two tags still in place, and one had a single tag. As of August 1983 when the turtles were 35 months old, three of the turtles that had both tags still attached at 1 year of age had each shed one tag. Of the other two turtles, one still had both tags, and one had the single tag that was present at 1 year of age (Table 1).

Two of the 169 turtles released have been resighted after a sufficient interval to yield further information on tag retention. Five others were reported washed or crawling

Figure 1. Size 1 Monel® and size 681 Inconel® tags on the right front flipper of a yearling Hawaiian green turtle. The size 1 tag was attached at 1 month of age.

ashore during the first 2 months following release. The two longer-term resightings involved turtles 22 and 32 months of age. Both retained the two small tags present at the time of release. During their time in the wild, the turtles had grown from 29.5 to 33.6 cm, and from 27.2 to 36.0 cm. The 22-month old turtle was found speared just 3 km from its release site on the Island of Oahu. The 32-month old animal was released at the same site but was captured alive in a net 5,600 km away, at Truk, in the western Pacific.

DISCUSSION

Contrary to earlier reports, the external tags used in this study showed impressive retention rates. The success achieved is probably because small metal tags have not been fully tested on the front flipper. Another key factor may be that the tags used in the present study only showed minor corrosion. Corrosion is known to be an important factor in tag loss experienced in some research programs. Although long thought to be one of the better alloys available for turtle tags, Monel® is now known to corrode in a highly variable and sometimes severe fashion, even on turtles within the same population. If Monel® flipper tags were previously used on hatchlings by other workers, the tag shedding they observed may have been mainly due to corrosion. Tag corrosion and various other factors affecting tag retention have been discussed in Balazs (1982*a*).

Since late 1976, size 681 flipper tags made from Inconel®, an alloy far superior to Monel® in corrosion resistance, have been used on adult and immature green turtles in Hawaii. No corrosion has been seen in these tags, although some tags are still shed from tearing and other factors. Placing two or more tags on each turtle has greatly offset this problem (Balazs 1983). Inconel ® tags are not currently available due to high production costs. However, a company in Western Australia (Stockbrands Co. Pty. Ltd. of Mt. Hawthorn) has recently offered titanium flipper tags at a reasonable price ($120 per 1,000). Titanium has nearly as high corrosion resistance as Inconel® (LaQue 1975). The author and C. J. Limpus (Queensland National Parks and Wildlife Service, Townsville, Australia) have arranged for the manufacture of titanium tags equivalent to the size 1 Monel® tags tested in the present study. Future evaluations on hatchlings will therefore be possible using a product that is superior to Monel® in corrosion resistance.

Previous workers tagging hatchlings often stressed the need for a tag to persist into adulthood. The protracted time to maturity, and the increasing level of research now being conducted on immature turtles in the sea, now seem to make this goal less critical. Similar information can probably be gathered by catching wild juveniles already tagged as hatchlings, and retagging them with larger tags as needed.

ACKNOWLEDGMENTS

Helpful comments on a draft of this note were provided by Larry Ogren, Harold Hirth, Nicholas Mrosovsky, and C. Kenneth Dodd.

Table 1. Growth and tag shedding of five green turtles retained in captivity from 12 to 35 months of age.

	Straight carapace length (cm)		Increase in growth (cm)	Size 1 tags	
	12 months	35 months		Right[1]	Left[2]
1.	20.9	41.8	20.9	Shed	On
2.	24.3	46.7	22.4	Shed	On
3.	20.0	40.2	20.2	On	Shed
4.	24.6	40.3	15.7	On	On
5.	22.0	41.4	19.4	On	[3]

[1]Tags initially put on at 1 month of age when the turtles ranged 7-10 cm SCL.

[2]Tags initially put on at 6 months of age when the turtles ranged 15-19 cm SCL.

[3]Tag not present at 12 months of age.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

NOTES ON THE REPRODUCTIVE BIOLOGY OF AUSTRALIAN PYTHONS, GENERA *Aspidites, Liasis* AND *Morelia*

Snakes of the family Boidae (pythons and boas) are among the largest and most spectacular reptiles, and consequently are often maintained in captivity. Hence, despite the scarcity of studies on natural populations (e.g. Hoyer 1974), considerable information is available on the reproductive biology of captive specimens (e.g. Ross 1978). One finding of great interest is that female pythons do not desert the eggs after oviposition (as is the general rule in reptiles), but instead coil around the clutch and defend the eggs against potential predators. In some, and perhaps all species, the female warms the clutch by metabolic heat production through muscular contractions of her body ("shivering thermogenesis") (see Shine 1985, for a review). Although about half of the world's python species are restricted to Australia, these forms have attracted less study than the Asian or African species. The present paper (i) provides information on reproduction of captive *Aspidites melanocephalus, Liasis fuscus, Morelia amethistina, M. oenpelliensis* and *M. spilota;* (ii) describes natural nest sites and thermal regimes of four *M. spilota* clutches; and (iii) reviews published literature on reproductive biology of these species.

BLACK-HEADED PYTHON, *Aspidites melanocephalus*

This species is found over a wide area of northern Australia, and was studied by us near Townsville in coastal Queensland. In this region it is primarily nocturnal (20 of 24 specimens seen in the field were active at night) and feeds on a variety of vertebrate species. Captive specimens often refuse to feed on rats or mice, but readily accept other snakes as food.

Four *A. melanocephalus* were maintained in captivity in Townsville. The two males measured 1.9 and 2.1 m total length (TL), and the females 1.5 and 2.0 m. The snakes were housed separately in cages measuring 1.1 x 0.5 m, with artificial heating. Based on experience with other locally-occurring pythons *(Morelia spilota, Liasis fuscus),* we judged that mating in *A. melanocephalus* should occur in late winter or early spring (July-September). Hence, the snakes were placed together on 20 June 1981.

Mating occurred immediately with both pairs (Fig. 1). The males moved constantly about the cages, pressing their tails beside and under the females' tails. In the initial matings, the males persistently raked their "spurs" into the sides of the females' bodies near the cloaca. The spurs were raked rapidly (approximately two to three strokes per second) and vigorously. Spur use was seen only at the initial matings. Copulation was observed at all times of the day and night, but most frequently in early mornings (0800 h).

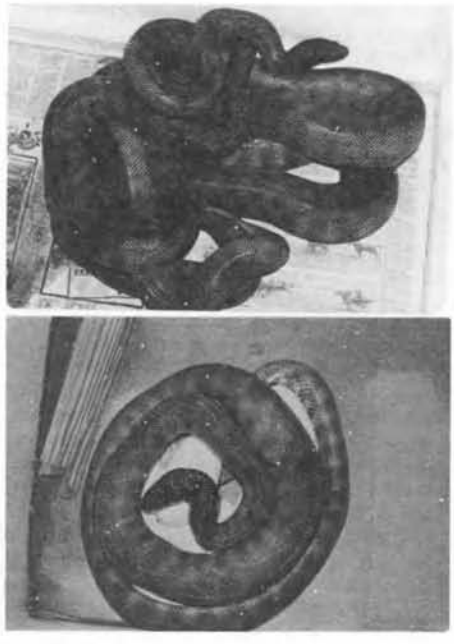

Figure 1. Upper: mating of captive *A. melanocephalus.* Lower: female *A. melanocephalus* coiled around clutch of eggs.

Duration of copulation was difficult to determine, but on at least one occasion exceeded 150 minutes.

When the two males were introduced to the same cage (without females), the larger male immediately began biting and constricting the smaller male vigorously. The snakes were forcibly separated and the smaller male removed and replaced by a female. The large male showed no signs of aggression towards this female. However, removal of the female and reintroduction of the other male instantly resulted in attack by the large male. This procedure was repeated once more with the same results.

Both females were noted to show slight swelling of the posterior half of the body in early September. The females at this time were observed to lie with their ventral surfaces facing outward or upward for long periods. The smaller female had returned to her usual proportions (i.e. no swelling) by early October and began accepting food. The swelling in the larger female gradually increased in size, and this snake did not feed.

Eight eggs were laid by the larger female on 12 November, between 1100 and 1730 h. The eggs were laid in a loose group before being drawn together by the female and encircled by her coils. The eggs were supported off the floor by the female's body. Spasmodic "shivering" bouts, each of less than 20 seconds duration were observed (Fig. 1).

The eggs were removed in a single adherent mass, and incubated in moist vermiculite at 30° C (range 29.5 to 31° C). Egg dimensions averaged 9.2 (s.d. = 0.6) x 5.2 (s.d. = 0.2) cm. A "window" was cut in one egg after 55 days incubation, revealing en embryo which was fully-formed but only lightly pigmented. Hatching occurred on 16, 17 and 18 January (one, two and five eggs, respectively). The neonates emerged 24 to 30 hours after initial slitting of the shells. The hatchling pythons

(two males, six females) averaged 61.9 cm snout-vent length (SVL) (s.d. = 1.1, range 60 to 63 cm), 68.6 cm TL (range 66 to 70) and 94.4 gm mass (s.d. = 3.2, range 89 to 98 cm).

The young snakes began feeding (most on mice) 20 to 37 days after hatching. At three months (16 April) they averaged 76.6 SVL (range 71 to 84) and 258 gm mass (range 195 to 280). By twelve months, the juvenile *A. melanocephalus* averaged 124 cm SVL (range 96.5 to 144) and 748 gm (range 425 to 1080). By twenty-four months of age, they averaged 174 cm SVL (132 to 198) and 2150 gm (1100 to 3700).

Another female *A. melanocephalus* from Weipa, Qld., laid 10 eggs on 13 October, but none hatched. Previous records of *A. melanocephalus* reproduction reveal considerable variation in egg size, hatchling size, and incubation period. Whereas we recorded hatchlings of 69 cm (94 gm), hatching after 66 days, Boos (1979) recorded hatchlings of 50 to 53 cm (45 to 60 gm), hatching after 93 days. The prolonged incubation probably is due to the lower temperature (24-27°, versus 30°) at which Boos (1979) incubated the eggs. Hatchlings recorded by Murphy et al. (1981) were intermediate in size (60 cm, 81 gm) and incubation period (83 days) between the above values. Clutch sizes of *A. melanocephalus* range from five to twelve eggs, with specific records of 5, 6, 7, 8, 9, 10, 11 and 12 (Gow 1976; Boos 1979; Murphy et al. 1981; P. Harvey, pers. comm.; present study).

WATER PYTHON, *Liasis fuscus*

The northern Australian water python has recently been moved from *Liasis* to *Bothrochilus* (Cogger et al. 1983). However the ICZN is currently considering an application that would cause *fuscus* to revert to *Liasis* (H. Cogger, pers. comm.). There is disagreement over whether the Australian form should be placed in the species *mackloti* (McDowell 1975) or *fuscus* (Cogger 1975).

A specimen from Townsville, Qld., deposited 19 eggs (four infertile) on 15 November 1982. The eggs were laid at intervals of approximately 10 minutes, with the first at 0610 h and the last before 1030 h. Although the male caged with this female had shown courtship in early August, no copulation had been observed. The 15 fertile eggs varied in mass from 51.8 to 59.1 ($\overline{X}$ = 55.0, s.d. = 2.2), in length from 4.7 to 5.68 cm ($\overline{X}$ = 5.2, s.d. = 0.3) and in width from 3.7 to 4.4 cm ($\overline{X}$ = 4.0, s.d. = 0.2). The four infertile eggs were much smaller, with masses of 20.4 to 22.4 gm ($\overline{X}$ = 21.1), lengths of 4.0 to 4.2 cm ($\overline{X}$ = 4.0), and widths of 2.5 to 2.6 cm. The eggs were incubated in moist vermiculite at 30° C (range 29.5 to 31.0). Hatching occurred from 27 to 31 January; of the 15 fertile eggs, 14 produced normal young and one a deformed individual with a severe body kink. The 14 normal neonates averaged 31.4 gm (s.d. = 4.4, range 23 to 37), 35.5 cm SVL (s.d. = 2.8, range 31.0 to 40.5) and 41.5 cm TL (s.d. = 3.0, range 35.7 to 46.9).

Two years after the breeding recorded above, the female oviposited again (17 eggs on 4 November 1984). The eggs were tightly adherent and were incubated by the female, with 14 young hatching from 10 to 13 January 1985. The neonates averaged 56.1 gm (s.d. = 5.2, range 45 to 65), 41.3 cm SVL (s.d. = 2.3, range 36.0 to 44.5) and 48.6 cm TL (s.d. = 2.7, range 42.4 to 52.3). Hence, they were significantly larger in all these respects than were the previous clutch from the same female. Data are also available for a clutch laid on 28 October 1984 by a captive *L. fuscus* in Townsville. The clutch of 16 eggs had a mass of 999 gm, with the female having a mass of 2200 gm after oviposition (Relative Clutch Mass = 0.45). Eleven fertile eggs averaged 77.7 gm (s.d. = 4.4, range 69 to 84), with length 66.5 mm (s.d. = 2.2, range 64 to 72) and width 45.3 mm (s.d. = 1.8, range 41 to 48). Five infertile eggs averaged 28.8 gm (27 to 31 gm), and 44 x 33 mm. Following artificial incubation at approximately 30 to 31° C, the eggs hatched from 6 to 8 January 1985. The 11 neonates averaged 60.4 gm (s.d. = 4.3, range 52 to 67), 42.6 cm SVL (s.d. = 2.7, range 38.5 to 46.2), and 50.1 cm TL (s.d. = 2.7, range 46.3 to 53.7).

Another female water python maintained in Renmark, South Australia, mated in June and July, and laid 14 eggs on 17 August 1979 (J. Bredl, pers. comm.). One egg was measured and found to be 55 x 45 mm and 55.0 gm mass. The female coiled around the eggs, reacted aggressively to interference by humans, and underwent regular "shivering" behaviour on cool days (J. Bredl, pers. comm.). The eggs were removed from the female on 28 September, and artificially incubated at 28 to 30° C. Hatching occurred on 18 to 25 October, and the offspring ranged from 43 to 47 cm TL (30 to 40 gm mass). Another specimen of 250 cm length laid 16 eggs on 2 November; artificially incubated at 30° C, these hatched on 12 to 19 January (G. Parker, pers. comm.). Captive specimens maintained by B. Barnett (pers. comm.) produced 11 to 23 eggs, with a mean clutch size of 17. Finally, three female *L. fuscus* from the Townsville region oviposited in late November: fecundities were 6, 19 and 20 eggs.

Published data on reproduction of *L. fuscus* are consistent with the information given above. Murphy et al. (1981) noted a clutch size of 12 (eggs 63 x 40 mm, 57 gm), hatching after 74 days at 32° C, with hatchlings measuring 44.1 cm length (30.6 gm). There is some doubt, however, whether the specimens providing this record were from Australia (*L. fuscus*) or New Guinea (*L. mackloti*). Boos (1979) described a 160 cm female *L. fuscus* mating in August and October and laying 11 eggs on 10 October. These were maternally incubated and hatched after 57 to 61 days. Other published records of reproduction in *L. fuscus* note clutch sizes of "approximately 30" (Kinghorn 1964), "up to 11" (Gow 1976), 10 to 15 (McPhee 1979) and 11 (Ross 1978).

AMETHYSTINE PYTHON, *Morelia amethistina*

This species is the largest Australian python, attaining lengths up to 8.5 m. Its generic allocation has recently been changed from *Liasis*, to *Python*, to *Morelia* (Cogger et al. 1983). It is found only in coastal tropical Queensland; the two specimens kept by us were both collected in Cairns. The male was collected in April 1976 and measured 140 cm total length; at the time of successful reproduction (April 1982) it measured 270 cm total (234 cm SVL) and had a mass of 4.5 kg. The female measured 215 cm TL in October 1977, and 270 cm TL (231 cm SVL) and 3.0 kg in April 1982. The specimens were kept in Brisbane and housed together in a cage 2 m x 1 m x 1 m with artificial heating and natural (Brisbane) photoperiod.

The snakes were found *in copulo* at 2300 h on 24 September 1981. Their tails were intertwined and the rest of their bodies stretched out loosely side-by-side. Copulation continued for at least 60 min and was repeated on the next night. The female bled from the cloaca at each mating. From the time of mating, the female refused to feed and spent long periods basking. She often lay with her ventral surface facing outwards or upwards.

Seven eggs were deposited on 26 December 1981, and the female coiled tightly around them. No "shivering" was observed, but temperature readings from within the coils revealed a constant 30° C over 16 measurements during 8 days and nights. (Measurements taken daily at 0630 and 1900 h.) Cage temperature ranged from 28° to 30° C over this time. The eggs were removed on 5 January. They were tightly adherent and the seven eggs had a mass of 700 gm. The female began to feed normally after the eggs were removed.

The eggs were incubated at 29 to 31° C on moist vermiculite (50% water by weight), and one egg hatched on 10 April, 105 days after laying. Another egg was slit on 11 April, three on 12 April, and one on 13 April. The last egg was opened artificially on 13 April, revealing a live neonate which then emerged successfully. Most neonates remained inside the eggs for 48 h between the time of first slitting the shell, and final emergence. All neonates were light brown in colour, and were not as distinctly reticulated as the adults. The hatchlings comprised four females and three males, with a mean SVL of 54.1 cm (s.d. = 1.5, range 52.0 to 56.0), mean TL 63.9 cm (s.d. = 1.6, range 61.0 to 66.0 s.d. = 1.6), and mean mass 60 gm (s.d. = 1.0, range 58 to 61).

There are few published reports of reproduction in *Morelia amethistina* with which to compare our data. Shivering thermogenesis has been noted by Boos (1979). Fecundity has been estimated at 19 (Pope 1969; McPhee 1979) and 10 to 20 (Gow 1976), whereas Boos (1979) provides data on two clutches of 7 and 12 eggs. The incubation period reported by Boos (on a maternally-incubated clutch) was shorter than that observed by us (78 versus 106 days), but the hatchlings were of similar size (64 cm, 50 to 60 gm).

CARPET PYTHON, *Morelia spilota*

This species is one of the most common and widespread Australian pythons. Two brooding female *M. s. variegata* were discovered in suburban Brisbane in January 1982, and one in January 1985. The first snake (total length 215 cm) was under a pile of iron and "fibro" building materials (Fig. 2), and had been observed by workmen to emerge and bask in the sun each morning for the preceding week. When the material covering the python was lifted, she was seen to be tightly coiled around a mass of eggs (Fig. 2). She was very aggressive, striking vigorously and repeatedly. The probe from an electronic thermometer was inserted between her coils, and three readings were taken over the next

Figure 2. Upper: sheet of iron under which brooding female *M. spilota* located. Lower: position of snake and eggs when iron lifted.

week without disturbing the snake. All readings (taken at 1000, 1430 and 1545 h) were 30° C, whereas maximum air temperatures over this period averaged 28-30°.

The snake and eggs were collected on 9 January. The adherent mass of 23 eggs (two of which were discoloured and clearly dead) had a mass of 900 gm. As soon as she was placed in a cage, the female coiled around the eggs. Again, temperatures taken four to six times per day within the python's coils remained at 30° C, except for one reading. At this time, air temperature in the cage fell to 26° C (rather than the usual 28°) and egg temperature was 34° C. "Shivering" behaviour was not observed.

At 0830 h on 14 February, the python was seen to be draped only loosely around the eggs. Eleven of the eggs were slit, with several hatchlings having their heads protruding from the shells. The first four neonates fully emerged approximately 11 hours later. All 21 pythons had emerged by 16 February, although one neonate died soon after emergence. The hatchlings comprised ten females and eleven males, with mean mass 30.3 gm (s.d. = 2.6, range 24 to 35 gm) and mean SVL 39.3 cm (s.d. = 2.2, range 32 to 41 cm).

The second brooding female *M. s. variegata* was found on 25 January 1982 in a suburban garden. The snake (TL 180 cm) was coiled tightly around her eggs on a mound of dried grass clippings. She was very aggressive when disturbed. Temperatures within her coils, recorded over several days, remained at 30° C. The python was not seen to leave the eggs at any time, even during heavy rain. However, on 14 February she was seen to be draped only loosely around the eggs. The temperature within the coils at this time was the same as air temperature (26° C). Closer inspection revealed that only seven eggs had been laid, and the rest retained within the female's body. The snake and eggs were collected, the eggs incubated in vermiculite at 30° C, and the remaining uterine eggs (badly decomposed by this time) surgically removed from the female python. Four of the incubated eggs were slit on 19 February, and the hatchlings had emerged by the next morning. The remaining eggs were opened on 22 February; one contained a dead full-term embryo, the other a live specimen. The five live hatchlings were all males with a mass of 20 to 22 gms ($\bar{X}$ = 21 gm, s.d. = 0.7) and measured 37 to 39 cm SVL ($\bar{X}$ = 37.9 cm, s.d. = 0.7).

Another Brisbane specimen attending a clutch of 15 eggs was found in January 1985, between bales of hay in a suburban yard. The female was observed to regularly leave the eggs to bask in the morning sun at a site about three metres from the eggs. The nest site between the bales was moist, being protected by another two overlaying bales. Temperatures measured at 1100 h were 28° C between the snake's coils, and 29° C in the surrounding air. The python abandoned this clutch following a heavy hail storm on 19 January, so the clutch (total mass 540 gm) was moved and artificially incubated at 25 to 29° C. Hatching occurred on 21 to 24 February 1985, with neonate masses of 22 to 25 gm, and approximately 40 cm total length (R. Drams, pers. comm.).

A fourth brooding carpet python was discovered on 15 January 1985 in Townsville. As in the previous case, the clutch was laid at ground level between and under bales of hay. Readings at 1300 h revealed an air temperature of 31° C, and a clutch temperature of 32° C. The female returned to the clutch after disturbance on two occasions. The clutch of ten eggs had a mass of 385 gm, and the female 680 gm (145 cm SVL). Following removal to the laboratory at 31° C, the eggs hatched on 11 February 1985. Neonates averaged 29.7 gm (s.d. = 1.5, range 27 to 32), 40.1 cm SVL (s.d. = 1.2, range 37.3 to 41.5), and 47.2 cm TL (s.d. = 1.2, range 44.4 to 48.7).

Two captive *Morelia s. variegata* maintained in Townsville, northern Queensland, were observed to mate several times in August, always in the early morning. Mating was first recorded on 4 August 1982, and last recorded on 26 August 1982. The female laid twelve fertile eggs, beginning at 1930 h on 23 November 1982 and finishing at 0630 h the following morning. She coiled around ten of the eggs, but all developed fungal infections and failed to hatch. The twelve eggs averaged 50.5 gm (s.d. = 1.6, range 48.7 to 54.3), and measured approximately 55 x 38 mm (range in lengths 51.7 to 71.5; range in width 30.2 to 40.8).

Data were obtained on another Townsville pair of *M. spilota* in the following year. The male (255 cm) and female (230 cm) mated on 11 August, beginning at 1730 h (duration of mating at least 90 minutes). From mid-September the female was often seen basking with the ventral surface turned upward or outward. Twenty-nine eggs were laid on 16 November 1983. Only four of these eggs had normally calcified shells, and most of the abnormal eggs failed to develop. The female coiled around the eggs, with spasmodic "shivering" bouts persisting for several days after the eggs were removed on the day of oviposition. The clutch had a mass of 1609 gm, and the female 3700 gm after oviposition. Three infertile eggs were smaller (approx. 52 x 34 mm, 46 gm) than the other 26 fertile eggs (length: $\bar{X}$ = 63.1 mm, s.d. = 3.1, range 57 to 68; width: $\bar{X}$ = 41.7 mm, s.d. = 1.9, range 39 to 45; mass: $\bar{X}$ = 58.5 gm, s.d. = 2.8, range 52 to 63). Only six of these eggs, incubated at 30° C, hatched: on 17 January (one), 18 January (four), and 20 January (one). The hatchlings averaged 37 cm SVL (s.d. = 1.8, range 34 to 39), and 26 gm mass (s.d. = 2.0, range 25 to 29).

Another captive *M. spilota* in Townsville laid 11 eggs on 28 November 1984 (mean egg mass 49.1 gm, s.d. = 4.0, range 44 to 59 gm; dimensions 48 x 39 mm to 65 x 39 mm). The clutch mass was 540 gm, and the female 2600 gm after oviposition (RCM = 0.21). Following incubation at 30 to 31° C, all eggs hatched on 2 February 1985. Hatchlings averaged 33.8 gm (s.d. = 1.3, range 32 to 35), 41.0 cm SVL (s.d. = 1.1, range 39.8 to 42.9) and 49.1 cm TL (s.d. = 1.1, range 48 to 51.2). Agonistic behaviour by male *M. spilota* was recorded on 18 September 1985, when two males and two females (all between 230 and 280 cm length) were placed together. Both males began hissing and moved rapidly around the cage. When the pythons were next inspected 50 minutes later, one male and one female had many deep lacerations on the posterior thirds of the bodies, mostly around the cloacal region. The cuts were up to 60 mm long and 10 mm deep, and apparently inflicted by the teeth (or spurs?) of the other male.

One final record comes from a female python from Wingham, N.S.W., intermediate in coloration between the subspecies *Morelia s. spilota* and *M. s. variegata*. The snake was found coiled around a clutch of 22 eggs in *Lantana* scrub close to a stream. During a short period after capture and removal to a cage, the female continued to brood the eggs, and was aggressive when disturbed. She refused food until the eggs were removed, at which time she commenced feeding. Following a brief (6-day) period of artificial incubation, the eggs hatched to produce neonates 37.5 to 43 cm TL (L. Naylor, pers. comm.).

There have been few previous observations of female pythons brooding eggs in the wild. Published records of reproduction in *Morelia spilota variegata* include clutch sizes of 12 to 47, with specific records of 12, 14, 15, 16, 26, 32, 34, 40, 47 (Fleay 1960; Covacevich 1970; Ross 1978; Boos 1979; Banks 1979). Similar fecundity characterizes the other subspecies, *M. s. spilota* (9 to 54: Boos 1979; Banks 1979; Gow 1976; McPhee 1979; Harlow and Grigg 1984). Clutch sizes of 14 and 16 eggs were recorded by B. Barnett (pers. comm.). Incubation periods apparently are variable, with extremes of 37 to 103 days (Boos 1979; Banks 1979). Hatchling sizes reported by us (37 to 41 cm, 21 to 30 gm) are similar to those previously published (38 cm - Fleay 1960; 30-38 cm - Gow 1976, 1977; 30-45 cm - Banks 1979).

OENPELLI PYTHON, *Morelia oenpelliensis*

A female of this large and rare species, collected in the Arnhemland escarpment on 29 September 1984, laid a single egg with a mass of 184.9 gm (measuring 120 x 50 mm) on 20 October 1984. Nine remaining eggs were

removed surgically on 27 October 1984 and were of similar size of the first egg. All were apparently fertile but failed to develop. Egg mass averaged 185.8 gm (s.d. = 8.8, range 176 to 203 gm), and dimensions ranged from 90 x 60 mm to 105 x 60 mm. No previous data on *M. oenpelliensis* reproduction are available.

DISCUSSION

Data gathered in the present study generally are consistent with the results of previous studies. Maternal egg-brooding was seen in all four of the species in which reproduction in captivity was observed. Temperature measurements and/or observations of "shivering" suggest that females utilize metabolic thermogenesis to warm the eggs in all four forms. Our measurements of clutch temperature in *M. spilota* are, to our knowledge, the first made of brooding pythons in the field: although scanty, they are consistent with the prediction that maternal thermogenesis may enable a high and constant temperature to be maintained in the egg clutch (e.g. Harlow and Grigg 1984).

Our study also reveals interspecific similarities in some reproductive parameters (e.g. times of mating and oviposition) and differences in others (e.g. egg and offspring sizes; incubation periods). Many of these differences are surprising. For example, *A. melanocephalus* has a much larger egg and offspring, relative to adult body size, than the other species studied. Indeed, the hatchlings of *A. melanocephalus* are considerably larger than those of the amethystine python, *M. amethistina*. Nonetheless, the incubation period for these large offspring is very brief, similar to that for the much smaller offspring of *L. fuscus* and *M. spilota*. Additionally, the growth rates recorded for captive neonates of *A. melanocephalus* are surprisingly high. Any attempt to interpret the evolutionary and ecological significance of such differences would be premature at the moment: comparative data on the reproductive biology and natural history of other Australian pythons are needed for such a synthesis.

ACKNOWLEDGMENTS

We are grateful to several reptile keepers who provided data on their charges: J. Roberts, J. Devenish, P. Harvey, J. Bredl, B. Barnett and L. Naylor. We thank the Queensland National Parks and Wildlife Service for permission to conduct these studies, and the Northern Territory Conservation Commission for the gravid Oenpelli python. Valuable comments on the ms were provided by D. Slip and R. Lambeck. We thank also Terri Shine and Sylvia Warren for typing this paper.

MAINTENANCE, EXHIBITION, AND BREEDING OF THE TAILED FROG, *Ascaphus Truei*, IN A ZOOLOGICAL PARK

Ascaphus of North America and *Leiopelma* of New Zealand are currently the only two genera in the family *Ascaphidae*, differing from other frogs by their amphicoelous vertebrae. They also share some primitive evolutionary anuran traits such as free bony ribs and the retention of two tail-wagging muscles, the pyriformis and the caudalipuboischiotibialis (Noble 1931; Stebbins 1954; Griffiths 1963; Duellman 1975).

Ascaphus truei, the only North American species and commonly called the tailed frog, inhabits the permanent cold water streams of the Coast and Cascade Mountain Ranges from southwestern British Columbia through western Washington and western Oregon to the northern California coast. This cryogenic anuran is also found in the northern Rocky Mountains of Idaho and Montana, the Wallowa Mountains of northeastern Oregon and the Blue Mountains of southeastern Washington, at timbered elevations ranging from sea level to 2000 m (Stebbins 1954; Behler and King 1979).

Unlike most other anurans the tailed frog lacks a tympanum and is voiceless (Noble 1931; Stebbins 1954; Behler and King 1979; Nussbaum et al. 1983).

A. truei is rare among frogs in using internal fertilization. *Nectophrynoides occidentalis*, a viviparous toad of Africa, is the only other anuran in which fertilization of the eggs is internal (Noble 1931; Cochran 1961; Browning 1973; Brown 1975). The male *A. truei* is unique, however, in possessing a vascular extension of the cloaca which is used during amplexus as an intromittent organ to transfer sperm into the cloaca of the female (Noble 1931; Stebbins 1954; Nussbaum et al. 1983).

After autumn mating the sperm overwinter in the female's oviduct. She lays fertilized eggs in the spring. These colorless balls of jelly are attached singularly or in strings to the undersides of rocks in mountain streams. The eggs hatch in approximately one month. The small black to brown larvae are equipped with a sucking disc around their mouthparts for holding onto rocks in fast-moving streams as they feed on algae and diatoms (Behler and King 1979; Nussbaum et al. 1983). Tadpoles metamorphose into froglets at two to three years of age. Adult frogs reach sexual maturity in their seventh year. Life expectancy is thought to be greater than 14 years (Daugherty and Sheldon 1982a).

Although field studies (Gaige 1920; Noble and Putnam 1931; Metter 1964a, 1964b, 1967; Landreth and Ferguson 1967; Wernz 1969; Brown 1975; Hailman 1982; Daugherty and Sheldon 1982a, 1982b) as well as laboratory studies (Noble 1931; Metter and Pauken 1969; Wernz and Storm 1969; Altig and Brodie 1972; Claussen 1973a, 1973b; Brown 1975; Hailman and Jaeger 1978; Green et al. 1980) have been conducted on *A. truei* there are no published reports on zoological exhibitry and husbandry of this species.

This study describes captive maintenance, display techniques, and attempts to breed tailed frogs over a two year period (April 1982 - April 1984) at the Washington Park Zoo, Portland, Oregon.

MATERIALS AND METHODS

Collecting. Adults and larvae were collected in the Oregon Cascade Mountains and the Oregon Columbia River Gorge. Specimens were located during all four seasons though they were more easily found during late spring and early summer. Animals were obtained during both daylight and nighttime hours (See Tables 1 and 2 for dates of capture). Frogs were captured by hand; a small mesh net proved useful for collecting larvae.

Plastic collecting vessels were cushioned against one another inside an ice-filled styrofoam container. Stream water from the collection sites was used as a transport medium for the tadpoles; moss was supplied to the frogs. Rocks and fallen branches were also taken to make the cages appear as natural as possible and to minimize the stresses of capture and captivity (Nace 1977).

Exhibit tank. The exhibit tank (75 x 25 x 45 cm) held approximately 8 l (6 cm) of untreated city tap water. Water for aquaria housing larvae was dechlorinated by aging.

A water pump was connected to 7.6 m of clear plastic tubing coiled inside an insulated, water filled, plastic bucket. This bucket was attached to the refrigeration unit of a commercial liquid cooler. To further cool the water, cube ice was added to the bucket sporadically in the winter and more often during warmer weather. Exposed plastic tubing was wrapped with 15.9 mm water pipe insulation. This cooling system kept the exhibit water temperature within the preferred range of 5° C to 12° C (Claussen 1975).

The filtration system consisted of a mechanical filter, which removed suspended material from the water, and a chemical (activated charcoal) filter, which removed dissolved gases, chlorine, and other chemicals. This system maintained a high quality, aquatic habitat for the animals. The filters were installed between the water pump and the chiller.

Smooth stones, with a diameter of 25 to 75 mm (Altig and Brodie 1972), were layered on the floor of the enclosure. A few larger stones, Douglas fir branches, and small ferns (Filicophyta) were added. The larger stones were angled against the front of the aquarium glass. An aerator was hidden under the stones.

The outside of the back and sides of the tank was covered with a neutral gray plastic. The cover of the exhibit tank was 6.4 mm hardware cloth framed in wood with cutouts for the outlet and pickup tubes. Clear plexiglass was placed over the screening. On top of the plexiglass, a 30 cm 20 watt fluorescent full spectrum lamp connected to an electrical timer provided lighting with the day/night cycle set to duplicate the natural photoperiod for Multnomah county, Oregon.

The exhibit tank was positioned near the entrance of the Cascades Stream and Pond Building and was therefore influenced by natural light, outdoor temperatures, and noise from the public hallway. Disturbances from these sources were believed to be minimal. A 75 x 45 x 0.95 cm piece of clear glass was placed between the front of the tank and the viewing area. The back of the tank projected into an animal keeper work area which had low noise levels but was heated to 15.6° C at night and 17.8° C during the day. The back and sides of the tank were enclosed in 25.4 mm styrofoam sheet insulation to minimize temperature influences from the work area.

Holding tanks. The off-exhibit holding area, the Herptile Quarantine Cold Room, was a small room, 2.7 x 2.1 x 2.7 m, inside a cement block building. An 11,000 BTU/hr window mount air conditioner maintained the temperature within the range of 5° C to 17° C with a mean of 11° C. Timed lighting, set to duplicate natural day/night cycles, was provided by a ceiling-mounted 1.2 m standard double fluorescent fixture with a white full spectrum lamp and a red lamp. Tailed frogs were housed in various sized aquaria ranging in capacity from 7.6 to 113.6 l. These holding tanks were furnished similarly to the exhibit tank.

Subjects and maintenance. A total of five male, four female, and 25 larvae of *A. truei* were captured for use in the study (Tables 1 and 2). A few tadpoles and 3-4 males were the primary exhibit subjects.

Female *Ascaphus* were introduced into the exhibit when adult males developed seasonal sexual characteristics as described by Gaige (1920), Noble and Putnam (1931), Metter (1964a), and Daugherty and Sheldon (1982a). The female frogs were removed after amplexus had been broken or after two days if amplexus had not occurred, then reintroduced at a later date.

Diet consisted of purchased or captive-reared 2-10 week old house cricket nymphs *(Achete domestica)*, flesh fly larvae *(Sarcophage bullata)*, mealworm larvae *(Tenebrio molitor)*, wax moth larvae *(Galleria mellonella)*, and sow bugs *(Oniscus asellus)*. Frogs were occasionally offered small local spiders: The long-bodied cellar spider *(Pholcus phalangioides)* and the American house spider *(Achaearanea tepidariorum)*. Frogs were fed up to three times per week *en masse*. Animals were occasionally fed individually in 3.8 l plastic or glass containers to be sure they were eating and to test food preferences (Fig. 1). Diet records were kept for individual animals and for groups. Each frog was examined and weighed monthly on a triple beam balance. Feces, uneaten and dead food items, and dirty water were removed from the tanks every few days. Complete water changes and tank cleanings were done once per month.

Exhibit. The exhibit enclosure was designed to achieve four purposes: 1) to recreate the microhabitat of a tailed frog in a Cascade Mountain stream, 2) to house and maintain *A. truei*, 3) to allow zoo visitors to see the frogs, and 4) to research the captive husbandry of this species.

Frogs were given a wide choice of temperature and humidity gradients. Temperature extremes ranged from the coldest water temperature of 5° C to the warmest air temperature, directly beneath the exhibit lamp, of 16° C. The plexiglass top and daily mistings kept the humidity level high. Stones, branches, and vegetation were placed at different levels so frogs had a selection of perch sites.

The absence of larval external gills and the reduction of lung size and lung vascularity in adults indicate that these animals rely mostly on cutaneous respiration requiring a cold environment with high oxygen levels. This was provided by the cold moving water and by the stone aerator. The bubbling action of the aerator also helped keep material in suspension, increasing the efficiency of the filtration system. The reduced lung capacity results in an increase in specific gravity of *Ascaphus*, facilitating submergence.

Tailed frogs, though fed during the day, ate at night and were therefore rarely observed feeding. When *Ascaphus* were observed feeding they usually reacted opportunistically, lunging at active food items. Frogs were rarely observed actively pursuing a live food item.

The frogs displayed a clear preference for spiders and crickets (Fig. 1). Test for significance of differences between two proportions was $Z = 2.24$, when $p < .05$.

Monthly weighings during the two year study period resulted in weight ranges, for male frogs, of 5.2 to 6.0 g (n=4) with an average of 5.7 g. Female weights ranged from 8.0 to 9.4 g (n=4) with an average of 8.8 g.

Because it was important that visitors see the frogs, several exhibit modifications were made to improve viewing. In an attempt to reverse the light cycle to show the frogs when they were most active, a one way mirror was substituted for the clear glass fronting the exhibit. This proved too dark for proper viewing. A red fluorescent lamp was substituted for the white lamp, but this also proved too

Table 1. Date frogs entered the collection, time in captivity, and disposition.

Animal #	Arrival date	Time in captivity	Disposition
82-1♂	18 March 1982	25 months	Alive in exhibit

dark for viewing. A more successful strategy was to arrange the enclosure substrate materials so that the frogs were visible even when they were hiding. *A. truei* concealed themselves by pushing between stones on the bottom of the tank, where they appeared squashed. Frogs hidden under the large stones angled against the front glass were thus visible. Branches, leaves, and moss were positioned in similar ways to provide hiding places visible to the public.

Despite these modifications, at times the frogs were difficult to see. Their brown, gray, and orange coloration provided excellent camouflage among the similarly colored stones. The zoo staff eventually agreed that careful scanning of the exhibit was part of the visitor's educational experience.

Because of their sympatric relationship in the wild (Stebbins 1954) an adult female *Rhyacotriton olympicus* shared the exhibit with *A. truei* frogs and tadpoles for more than a year.

Mortality. No adult frogs died during the study period. Two juvenile males died two months after capture without having eaten. Three larvae also succumbed within two months of capture. A two-month-old frog that metamorphosed from a captive larva died without having eaten. Almost a year after their capture, 15 larvae died after algae-covered rocks from a migratory waterfowl pond and from a zoo exhibit housing North American river otter *(Lutra canadensis)* were introduced into the larval holding tank. All died within 24 hours. Cause of death was not clinically determined.

Breeding. *A. truei* are typical anurans in that they are solitary most of the year. However, males and females may be found together during the fall breeding season (Wernz 1969), and Brown (1975) reports finding aggregations of females in July, at time of oviposition. Accordingly, males and females were housed separately.

When the adult males in the exhibit tank showed advanced development of transitory sexual characteristics, adult females were introduced. These characteristics included a series of small dark spines on the sides of the pectoral region, a rim of small dark tubercles on the edge of the lower jaw, the swelling of the forearm to two-to-three times its normal size and the appearance of large black horny pads on the inner palmar tubercle and the inner forearm (Gaige 1920; Noble and Putnam 1931; Metter 1964a; and Daugherty and Sheldon 1982a). Male and female frogs were introduced in the exhibit because it provided the best conditions for observation.

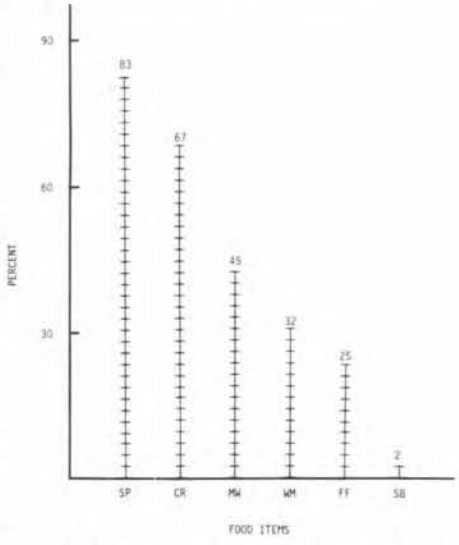

Figure 1. Percent of offered food items eaten by tailed frogs. Test for significance of differences between two proportions. Z = 2.24, when $p < .05$. SP, spiders; CR, crickets; MW, mealworms; WML, wax moth larvae; FF, flesh fly larvae; SB, sow bugs.

Three to four female *Ascaphus* were introduced into the enclosure at a time, and any of four behaviors resulted: 1) males and females ignored each other, 2) a male attempted to amplex a female but the female was not receptive, 3) a male inguinally amplexed a female but intromission did not occur, and 4) a male inguinally amplexed a female and intromission occurred. Females were never observed to initiate any contact behavior.

Mating occurred in accordance with recorded observations (Noble and Putnam 1931; Metter 1964b). At time of mating the external extension of the male's cloaca extended forward under the abdomen. The "tail" was maintained in this position by being engorged with blood, giving it a purplish appearance, and by two postpubal cartilages found in no other anuran (Noble 1931). When the male frog was successful in interlocking his arms around the female's pelvic region she assumed a sitting position with her legs drawn up. In this embrace the male was able to insert his cloacal appendage into the cloacal opening of the female.

Males with fully developed seasonal sexual characteristics were observed attempting to amplex juvenile and other adult male *Ascaphus* as well as the adult *Rhyacotriton* sharing the exhibit (Metter 1964b). An amplexed pair often attracted other males which attempted to amplex any part of the mating couple's bodies they could grab, sometimes holding on and dragging or being dragged around the tank for several hours before releasing their grips.

Pelvic amplexus with intromission was observed with three different pairs of frogs. These embraces were maintained for 28, 78, and at least 144 hours.

Mating pairs were occasionally handled to determine intromission and for photographic sessions to document these behaviors. The females often tried to jump away, dragging the amplexing males with them, but these disturbances did not cause the animals to break amplexus.

The first frog to metamorphose from a wild caught larva was a male which spent its entire captive life, 22 months, in the exhibit. This particular frog was more tolerant of light, noise, and other disturbances caused by captivity than wild caught adults. Also, it was often quite active in the daytime. The only time it was exposed to a female *A. truei* was when the latter were introduced into the tank for breeding. In the first year of its life, during these introductions, this frog hid and did not approach the females. It began to develop transitory sexual characteristics at 16 months. At 20 months it actively pursued adult female frogs and attempted amplexus with whichever part of the female's body was grabbed first. However, it has yet to be observed successfully amplexing an adult female.

Daugherty and Sheldon (1982a) stated that male *A. truei* do not show full development of skin tubercles (secondary sexual characteristics) until four years of age. It is well established that some mammals and reptiles can become sexually mature at an earlier age in captivity than in the wild (Hediger 1950; Kleiman 1975; Martin 1978). Although this phenomenon has not been proven for amphibians, our data suggest it may well exist for these animals as well.

CONCLUSIONS

This project resulted in the successful maintenance and exhibitry of *Ascaphus truei* in a zoological park. The husbandry techniques included clean, clear, cold, moving water; a relatively disturbance-free existence; varied food items providing adequate nutrition; a fairly constant forest-like environment; uncrowded housing conditions; a natural photoperiod; and the keeping of concise records.

Because of their propensity to hide and their lack of sustained activity, the uniqueness of *A. truei* is frequently not appreciated by the casual observer. Serious and interested zoo visitors, however, find the exhibit fascinating.

The production of eggs has not yet occurred, though several frogs bred readily. *Ascaphus* can be induced to ovulate by injection of amphibian pituitary gland extract or human chorionic gonadotropin (Noble and Putnam 1931; Wernz and Storm 1969; Brown 1975). It was hoped that by closely duplicating the frogs' natural habitat that eggs would be laid without the use of chemical stimulants. Though this has not happened as yet, further investigation is ongoing.

ACKNOWLEDGMENTS

This project was supported in part by grants from the Society for the Study of Amphibians and Reptiles Grants-In-Herpetology Program, and the American Association of Zookeepers. Thanks go to Jill Mellen and Lisa Rapaport for discussions and comments during the project. Nancy King and Ann Littlewood are especially thanked for making the manuscript readable. This research project would not have been possible without the continued and enthusiastic support of the Washington Park Zoo administration and numerous zoo personnel. Specifically, John Houck, J. Stephen McCusker, and Warren Iliff are gratefully acknowledged for their logistical support.

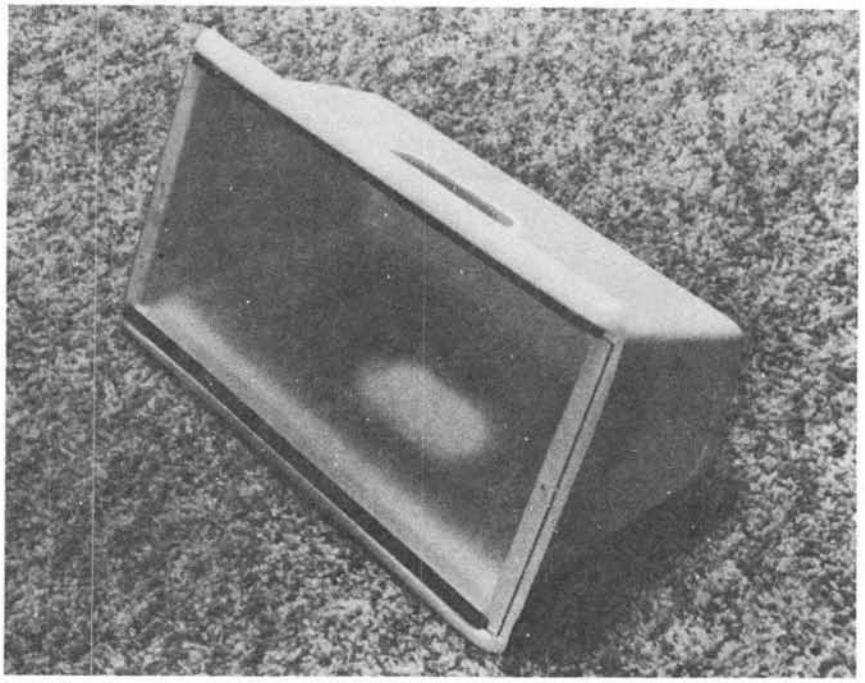
LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.



Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

CAUDATA

AMPHIUMA MEANS (Two-toed Amphiuma). **REPRODUCTION.** Salthe (1973. Cat. Amer. Amphib. Rept.:148.1-148.2) found few records regarding size of *Amphiuma means* at reproductive maturity and clutch size. Weber (1944, Copeia 1944:61-62) found a small (39 cm) *A. means* coiled around a clutch of 49 eggs, the smallest reproductive female and the smallest clutch recorded for this species.

A brooding female *A. means* and her eggs were accidentally dislodged from within a hollow log in Effingham Co., Georgia on 12 September 1983. The attended nest was located in a low place in a dry cypress-tupelo swamp which typically floods with the onset of winter rains and dries completely each summer. The amphiuma was coiled around 33 eggs, many of which ruptured when the log was opened. The extruded embryos closely resembled the newly hatched amphiumas described by Weber. Two of the intact eggs hatched in the laboratory two days later, after being immersed in tap water overnight;

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

the embryos were therefore at hatching stage when discovered.

The adult (total length = 36.9 cm; snout-vent length = 28.9 cm) is the smallest reproductive female *A. means* on record. In addition, her clutch is the smallest recorded for the species.

The female amphiuma and nest contents were preserved and deposited in the Savannah Science Museum Herpetology Collection (SMM 10456).

Submitted by **CHARLES W. SEYLE, JR.,** Savannah Science Museum, 4405 Paulsen Street, Savannah, Georgia 31405, U.S.A. ●

NECTURUS MACULOSUS (Mudpuppy). **JUVENILE ECOLOGY.** During the course of a snorkel survey of chestnut lamprey, *Ichthyomyzon castaneus,* at the Larsen Road bridge crossing of the Namekagon River, Sawyer County, Wisconsin (T-42N,R-8W, Sec. 16) on 16 September 1982, we discovered a female *Necturus maculosus* (total length = 24.5 cm; snout-vent length = 16.5 cm) with approximately 30-40 juveniles (mean total length = 31 mm, range = 29-32 mm, n = 17). All were located beneath a partially embedded concrete block at a depth of approximately 0.3 m in an area generally characterized by swift current, low turbidity, and abundant rubble and boulders over a gravel and sand bottom. The adult made no effort to escape and was easily captured with a handnet. The juveniles lay motionless on the bottom next to pieces of debris, swimming only to avoid the net; light dorsolateral striping on a dark background made individuals difficult to distinguish from the substrate (see Bishop 1926 N.Y. State Mus. Bull. 268:5-60 for illustrations).

The juveniles' mean total length, dorsolateral striping, and lack of conspicuous yolk correspond to the stage of development attained by captive-reared specimens at least 25 days after hatching (Bishop op.cit.). Since Bishop observed hatching in mid-July, it is clear that the Namekagon specimens either hatched at a later date or grew more slowly than his New York specimens. Occurrence of juveniles in the presence of an adult female, which had an empty gastrointestinal tract, suggests the possibility of maternal guarding of offspring for some time subsequent to hatching. Our observations indicated that juveniles are subject to predation; specimens allowed to drift in the current were consumed readily by common shiners, *Notropis cornutus,* and hornyhead chubs, *Nocomis biguttatus.* Similarly, Shoop and Gunning (1967, Copeia 1967:732-737) reported predation by fish on juvenile *N. beyeri.*

The stomach contents of 16 juveniles preserved in formalin (Table 1) provide information on the first exogenous food of mudpuppies, since yolk is present in smaller individuals (Bishop op. cit.). All 16 individuals contained food, and all food items were of types expected in a benthic crevice microhabitat. Early instars of aquatic insect larvae were the most important food item in terms of relative size, frequency of occurrence among stomachs, and numbers. Some small sand grains and algal filaments were ingested incidentally (e.g., some were clutched in the claws of insect larvae), but the relative size of some larger particles was such that they probably were ingested intentionally (perhaps mistaken for living prey when moving in a current).

Table 1. Stomach contents of 16 juvenile *Necturus maculosus.* All stomachs contained food.

	Number	Number of stomachs
Chironomid larvae	8	6
Dipteran pupae	1	1
Hydropsychid larvae	7	7
Mayfly naiads	4	2
Unidentified insect fragments	—	11
Hydrocarinids	15	9
Algal filaments	—	3
Sand grains	—	11

The adult and 16 juveniles analyzed for stomach contents in this study have been deposited in the University of Wisconsin-Madison Zoological Museum (H22546).

SAURIA

HELODERMA SUSPECTUM CINCTUM (Banded Gila Monster). **PATTERN/COLORATION.** On 14 August 1982, a Banded gila monster *(Heloderma suspectum cinctum)* was captured near a black basaltic lava flow, 10 km northwest of St. George, Washington County, Utah (total length = 424 mm; SV = 290 mm; mass = 273 g). The pattern and coloration of this lizard differ from the original description of *H. s. cinctum* given by Bogert and del Campo (1956. The Gila monster and its allies. Bull. Amer. Mus. Nat. Hist. 109:1-238).

The dorsal pattern of *H. suspectum cinctum* typically includes four black chain-like double crossbands on a flesh-colored background; the pattern of the crossbands changes very little from hatchling to adult. The crossbands break up during maturation to form a reticulate pattern in the southern subspecies, *H. s. suspectum* (Bogert and del Campo 1956. op. cit.). In addition to the ontogenetic pattern changes noted by these authors, they also found a latitudinal gradient in color of the helodermatids wherein the lightest individuals were found in northernmost populations from Utah and Nevada.

In typical specimens from Utah the width of the black crossbands (hence the percentage of black color) is variable but flesh color, not black is the predominant color. In the specimen reported herein the pattern is reversed; black is the predominant color with some semblance of salmon colored bands on this black background (Figure 1). The color in this lizard is more "salmon color" than the "flesh color" of typical Utah gila monsters. (Colors 5 and 6 respectively in the Naturalist's Color Guide, Smithe 1975. Naturalist's Color Guide, Amer. Mus. Nat. Hist., New York).

Figure 1. Dark coloration in *Heloderma suspectum cinctum* from southwestern Utah (bottom) contrasted with typical pattern in this northern subspecies (top).

This specimen is being maintained at Utah State University as part of a current study on *H. suspectum cinctum* from Utah. As of November 1984 (total length = 425 mm; SV = 290; mass = 430 g) no changes in its pattern or coloration have been noted.

Black basaltic lava flows are a common geomorphic feature within the range of *H. suspectum cinctum* in Utah and these lizards often use the lava rocks for shelters (personal observation). Numerous desert reptiles are closely color-matched to their habitat background, including lava (Norris 1965. pp. 162-229. *In:* W. W. Milstead, ed. Lizard Ecology: A Symposium, Univ. of Missouri Press, Columbia, Missouri). A local former collector and Andrew Barnum of Dixie College, St. George, Utah have also infrequently observed this dark phase of *H. suspectum cinctum* in southwestern Utah.

The observations of Bogert and del Campo (1956. op. cit.) suggest that gila monsters from the northern extent of the species range, i.e., southwestern Utah, should show the lowest percentage of black color. Sightings of dark individuals from Utah suggest that in addition to the broad latitudinal trends discussed by these authors, other factors, e.g., selection to match background coloration of local habitat features, may also influence the pattern and coloration of this species.

My thanks to J. Glenn and J. A. MacMahon for their helpful comments on the manuscript. Financial support was provided by Utah State University Department of Biology and Ecology Center, Utah Division of Wildlife Resources Nongame Section, Utah Audubon Society, and a Sigma Xi Grant in Aid.

Table 1. Incidence of Cactus Spines on Red-lipped Lizards.

	Number of Lizards	Number with Spines	Percent with Spines	Spine Location on Venter		Spines per Individual Mean (Range)
				Anterior Half	Posterior Half	
Males	32	7	21.9	7	0	1.0
Females	28	4	14.3	9	5	3.5 (1-7)
Total	60	11	18.3	16	5	1.9 (1-7)

SCELOPORUS UNDULATUS ERYTHROCHEILUS (Red-lipped Lizard). **INJURIES.** Red-lipped lizards are common rock dwellers that inhabit the Black Mesa region of extreme northwestern Cimarron Co., Oklahoma. They are typically found on the sandstone formations and large pieces of lava surrounded by clumps of dense vegetation consisting of mesquite *(Prosopis glandulosa)*, hackberry *(Celtis reticulata)*, shrubby oaks *(Quercus* spp.), and prickly pear cactus *(Opuntia* spp.). Lizards spend a substantial portion of their time on the rocks basking, displaying, or resting in the shaded crevices, and are often observed on the ground under the vegetation during late morning hours.

During June 1983, sixty adult red-lipped lizards from the Black Mesa region were collected and examined. Eleven of the lizards had cactus spines in their forelimbs, particularly the toes. Twenty-one fresh wounds and scars were observed on the venter of the limbs and body. Cactus spines (2 mm to 16 mm in length) were removed from each of these injuries (Table 1). Fifteen of the cactus spines were embedded in or beneath the skin. Five spines penetrated muscle and were in the forelimbs, including a 6 mm spine that protruded completely through the brachium. In another lizard, a 16 mm spine was lodged in the abdomen. Scar tissue surrounded the exposed portion of this spine indicating that the lizard had been carrying it for an extended period. Despite this, the lizard looked healthy as did the other ten lizards carrying spines.

Cactus spine injuries could have occurred during aggressive interactions, escape from predators, or while feeding. The first two explanations seem unlikely. First, female red-lipped lizards do not exhibit the aggressive behavior of males (Ferner 1976, Am. Midl. Nat. 96:291-302). Therefore, injuries should be more prevalent on males if acquired while fighting, but this was not observed ($X^2 = 0.82$, $df = 1$, $p > .10$). Second, lizards climbing over cacti while escaping predators should have cactus spines randomly located in the anterior and posterior halves of the venter. Spines were found significantly more often in the anterior ($X^2 = 5.64$, $df = 1$, $p > .05$). Thus, cactus spine injuries probably occur while lizards are picking food items off the cacti. This is further supported because 14 of the 16 anterior spines were in the chin and distal regions of the forelimbs.

SERPENTES

ATRACTASPIS ENGADDENSIS ('En Gedi Mole Viper). **OPHIOPHAGY.** Feeding habits of Israeli reptiles are poorly known because local herpetologists seldom examine the stomach contents of freshly captured specimens. In captivity *Atractaspis engaddensis* Haas readily eats skinks and juvenile rodents (Kochva pers. comm.; Mendelssohn pers. comm.).

A live specimen of *A. engaddensis* caught at Tequa', southern Judean Hills, on 31 May 1984 by two soldiers (who were bitten) was sent for identification to the Department of Zoology from the Hadassa Hospital on Mt. Scopus (Drs. D. Gilon and E. Raz). After being removed from the transportation container the specimen (328 mm TL) regurgitated a little-digested colubrine snake, *Eirensis coronelloides* (Jan) (239 mm TL; 73% of the predator's length). Both specimens are preserved in the Zoological Museum of the Department of Zoology, Hebrew University of Jerusalem (HUJ-R 16391 and 16392) (Figure 1).

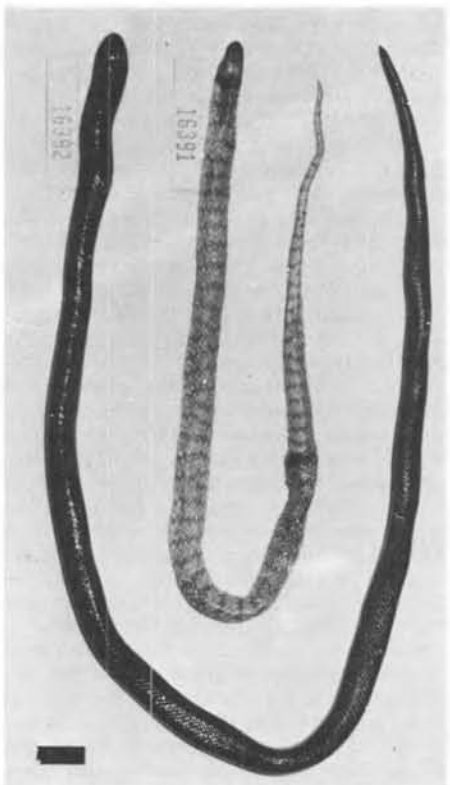

Figure 1. *Atractaspis engaddensis* (HUJ-R 16392) and the *Eirensis coronelloides* (HUJ-R 16391) which it regurgitated (photographed on 8 June 1984 before preservation, after having been frozen, by A. Niv and the submittor). Scale bar, 1 cm.

African species of *Atractaspis* are known to eat snakes in addition to skinks and rodents (FitzSimons 1962, Snakes of Southern Africa, Purnell, Cape Town; Pitman 1974, A Guide to the Snakes of Uganda, Wheldon & Wesley, Codicote). Interestingly the prey species in the present case, *E. coronelloides*, is suspected of possessing ophiophagous inclinations (pers. obs.).

Submitted by **YEHUDAH L. WERNER,** Department of Zoology, Hebrew University of Jerusalem, 91904 Jerusalem, Israel. ●

CANDOIA CARINATA (Solomon Island Boa). **OPHIOPHAGY.** *Candoia carinata* feeds on small lizards, frogs, birds, and rodents. Ophiophagy has not been reported to occur in the genus *Candoia*. J. Fauci (pers. comm.) informed me that a captive *Candoia carinata paulsoni* consumed a juvenile Madagascan boa *(Acrantophis dumerili)*. A similar incident of ophiophagy in another captive *C. carinata* is of interest.

A juvenile (ca 20.0 cm), captive-born female *C. carinata* was acquired on 13 April 1972. The specimen fed aggressively on new-born mice initially, and larger mice were consumed as growth occurred.

In the summer of 1976 the specimen (then ca 45 cm) and an adult (51 cm) Pacific rubber boa *(Charina bottae bottae)* were transferred to a 10 gallon aquarium. Continued observation showed no agonistic behavior between these specimens.

During the early morning of 8 July 1979, the *C. carinata* killed and ate the *C. bottae*. At the time, the former was about 62 cm, and the latter approximately 53 cm in length.

HYPSIGLENA TORQUATA OCHRORHYNCHA (Spotted Night Snake). **BEHAVIOR.** Snakes display a variety of antipredator behaviors including body inflation, tail displays, balling and others (Greene 1973. J. Herpetol. 7:143-161; Carpenter and Ferguson 1977. pp. 335-554, Biology of the Reptilia, Academic Press, NY). *Hypsiglena torquata* is a rear-fanged colubrid known to flatten the head and posterior body in response to predators (Carpenter and Ferguson 1977; Dundee 1950. Herpetologica 6:28-30). The notes presented here describe predator defensive behavior unreported for this species.

FURMONT REPTILE EQUIPMENT

Professional Equipment For The Herpetologist

SINCE 1972

FUHRMAN DIVERSIFIED offers you the broadest line of Professional Equipment for the Herpetologist and Zoologist. We presently supply over 250 Zoos and Aquariums, 100 Universities, 100 other organizations and thousands of individuals with the finest equipment available. Your satisfaction is guaranteed. Order early for fastest delivery.

FURMONT REPTILE HOOKS
- 14 Styles and Sizes
- Fixed Length & Collapsible Handles
- Mini to Boa Sizes
- Genuine "Stump Rippers"

REPTILE BAG STIK**
- Reptile Capture Bag Holder
- **U.S. Patent #3872834

SUP-R-BAGS
- Rip Stop Nylon Collecting Bags

HIDING BOXES
- 3 Sizes, ABS Plastic

FLEXI-NETS
- Flexible Hand Nets for Turtles, Lizards, etc.
- 12″ to 30″ Dia., 6″ to 32′ Handles, 4 Styles

STREAMLITE HANDLIGHTS
- AC and DC Rechargeable
- Ultra-High Intensity Quartz Halogen
- Field and Emergency Lighting

SNAREM-PLUS
- Noose Pole, 3′ to 6′ Lengths

WHITCO TONGS
- Best Field Tong Available

REPTILE SEXING PROBES
- 5 Sizes, Surgical Stainless Steel, Field Case

ELAPID ENVENOMATION KIT
- Under Development

PROTECTIVE APRONS/GLOVES
- Under Development

An adult male (249 mm SVL) was found 24 April 1976 under a piece of cardboard in a desert flatland creosote bush community, 11 km NE Scottsdale, Maricopa County, Arizona. When uncovered, he exhibited flattening of the head as previously reported (Dundee 1950). In addition, he attempted to escape by fleeing, but, when restrained by holding the posterior body, he coiled and writhed in a rhythmic manner, moved the tail in exaggerated lateral movements and attempted to hide his head under a body coil. This behavior continued as long as he was disturbed, but, if left unmolested for more than one minute, he uncoiled and crawled away. This sequence of behavior was observed several times. When picked up, the snake discharged the contents of his cloaca. At no time did he attempt to bite. These observations correspond to the stereotyped actions numbered 24, 49, 58, 98 and 102 listed for snakes by Carpenter and Ferguson (1977). I interpret these behaviors as attempts to divert the predator attack to the tail where the predator may receive a cloacal discharge or cause tail autotomy.

LAMPROPELTIS ALTERNA (Gray-banded Kingsnake). **AN UNUSUAL SLOUGH.** On 10 July 1983, a captive-born and raised male *Lampropeltis alterna* (864 mm total length, 22 months old) shed his skin after a normal opaque cycle. While removing the freshly molted skin from this animal's enclosure and inspecting the shed, one of us (MWH) observed that the shed skin had attached to it what looked like replicas of both the snake's hemipenes. The hemipenis "copies" were firmly attached to the vent and were in the normal position for these organs. While the molted skin was still moist the replicas were pliable. The base of each measured approximately 3 mm in girth and tapered out to a pointed end 16 mm long with no barbs or other visible protrusions. After several days of drying, the two replicas decreased in circumference and in length and were 10 mm for the left and 13 mm for the right. The total length of the dry molted skin was 914 mm. After observing hundreds of molted skins over the years we have never before seen a molted skin with abnormal attachments such as these, nor have we read any literature reporting such an occurrence. Fred B. Antonio of Gainesville, Florida inspected the skin and suggested that the two attachments could be from the anal glands, but this he had also never previously observed. The molted skin was destroyed by ants before other observations could be made to more completely describe these structures. Photographs were made of the shed before its loss (Figure 1).

NERODIA RHOMBIFERA (Diamondback Water Snake). **COLORATION.** Although instances of albinism in snakes are abundant and have been summarized by Dyrkacz (1981. Recent instances of albinism in North American amphibians and reptiles. SSAR Herp. Circular #11. pp. 1-32), records of other color aberrations without pattern changes are more rare. Hudson and Carl (1983. *Coluber constrictor flaviventris* Eastern Yellowbelly Racer. Coloration. SSAR Herp. Review 14(1):19) described specimens with yellow-orange ground color and orange markings. French (1981. Albinistic northern water snake in Alabama. SSAR Herp. Review 12(1):7) and Freed (1983. *Nerodia erythrogaster flavigaster* Yellowbelly Water Snake. Coloration. SSAR Herp. Review 14(3):75) described amelanistic water snakes *(Nerodia sipedon pleuralis* and *N. erythrogaster flavigaster*, respectively, both of which had pink to red eyes and flesh tone to tan for ground color and blotches.

On 20 August 1984 a litter of 23 *N. rhombifera* born in captivity to a normal mother captured in the St. Francis River bottoms, E. Paragould, Greene Co., Arkansas, by Mr. Ralph Routon, included five amelanistic neonates. Measurements made on 28 September were: male - 235 mm snout-vent/77 mm tail; females - 220/68, 230/68, 250/68, and 232/67. All snakes shed between 27 and 31 October. The pattern of all five neonates was normal, but color ranged from a yellowish-tan ground color with dark tan blotches to a tan ground color with brown blotches. The venters were light yellow with light brown triangular spots, except in one of the darker individuals, where it was almost uniformly yellowish-tan. Labials were almost totally yellow, and eyes were lightly pigmented, but slightly pink. Two snakes were of the lightest shade described, one was intermediate, and two were darker. The remaining littermates were of the normal dark gray to black coloration. Specimens are in the Memphis State University reptile and amphibian collection (Catalog numbers to be assigned).

NERODIA RHOMBIFERA (Diamondback Water Snake). **TWINNING.** A Siamese twin *N. rhombifera* was born on 24 August 1984 to a female captured by Mr. Ralph Routon, in the St. Francis River bottoms, E. Paragould, Greene Co., Arkansas. The snakes were joined ventrally from just inferior to the heart of the smaller individual and just superior to the heart of the larger individual to just superior to the ovaries of the larger individual. Deterioration of soft parts of the smaller individual, which was dead at birth, made determination of the inferior point of separation impossible. The snakes measured approximately 145/48 mm (snout-vent/tail) and 100/32. The position of each can be seen in Figure 1.

Twinning and anomalous births are not uncommon in snakes; one recent report on a *Python* (Clark and Tytle 1983. *Python molurus bivittatus* (Burmese Python). Morphology. SSAR Herp. Review 14(4):121) included both twinning and a dicephalic individual. Belfit and Nienaber (1983. A dicephalic kingsnake *(Lampropeltis getulus yumensis)* from Arizona. SSAR Herp. Review 14(1):9) reported on a dicephalic kingsnake and reviewed the literature on other instances of dicephaly. This is the first instance known to us of Siamese twinning in *N. rhombifera*. The specimen is in the reptile and amphibian collection at Memphis State University (Catalog No. will be assigned). We wish to thank Dr. Laverne Gurley for her time and effort in producing radiographs of the specimen.

Submitted by **RAY D. BURKETT** and **JAMES A. HUGGINS,** Department of Natural Sciences, Shelby State Community College, P.O. Box 40568, Memphis, Tennessee 38174-0568, U.S.A. ●

NOTECHIS SCUTATUS (Australian Tiger Snake). **FEEDING BEHAVIOR.** Shine and Covacevich (1983. J. Herpetol. 17:60-69) reported "unlike other Australian elapids, *O.* [*Oxyuranus*] *scutellatus* do not retain their initial hold on the prey until struggling ceases: the prey is released instantly after the strike." They then suggest that this "strike and release" feeding behavior is an adaptation to mammalian prey. Observations on captive tiger snakes support this suggestion.

Tiger snakes normally feed on both mammalian and amphibian prey (Shine 1977. Can. J. Zool. 55:1118-1128). During 1968-69 large numbers of tiger snakes (up to 30) were maintained in captivity at the University of New England, on a diet of live laboratory mice. Several hundred feeding episodes were observed over that period, involving about 50 individual animals. All snakes fed by "strike and release" behavior, and then, usually after a delay of about five minutes, followed the scent trail of the bitten mouse.

During 1971 a litter of 16 tiger snakes was maintained for three months on a diet of frogs. These animals did not release after striking the prey. An individual adult *Notechis* fed frogs in captivity fed in the same way. A wild tiger snake observed eating a frog similarly did not release the frog after capture (Heatwole et al. 1973. Hiss News-J 1:113).

These observations are consistent with the theory that tiger snakes employ "strike and release" feeding behavior for mammalian prey, and the more common "strike and hold" behavior for frogs. The former behavior "may be an adaptation to the retaliatory ability of mammalian prey" (Shine and Covacevich op. cit.). The high metabolic rate of mammals apparently allows the "strike and release" behavior to be successful (mice bitten by captive tiger snakes usually travelled less than a metre), whereas the lower metabolic rate of amphibians may allow prey to move further before death. That frogs presumably leave a discontinuous scent trail may also be a factor in the development of different feeding strategies for different prey.

Submitted by **GEOFFREY J. WITTEN,** Department of Anatomy and Physiology, Phillip Institute of Technology, Plenty Road, Bundoora, Victoria, 3083, Australia. ●

PYTHON MOLURUS BIVITTATUS (Burmese python). **COLORATION.** Albinism is a commonly reported anomaly among reptiles (Gilboa and Dowling 1974. HISS Publ. Herp. 6:1-11). Dyrkacz (1981. SSAR Herp. Circ. No. 11) described captive albino specimens that recovered normal pigmentation, indicating a metabolic rather than genetic etiology. However, he did not report the reverse, where normally pigmented specimens became albinistic. This note describes a normal *Python molurus bivittatus* that became leukistic at two years of age.

A normally colored hatchling female *Python molurus bivittatus* was purchased from a breeder in 1977. The snake remained normal for between 1-2 years. Then over the relatively short period of 1-2 months the skin pigment faded until the snake was almost pure white with no trace of a pattern. A few remaining dark spots along the body were noticed to fade with each ecdysis. In 1985, the snake is still leukistic (Figure 1). The only remaining pigment is in the dark eyes, an incomplete spearpoint pattern covering the top of the head (Figure 2) and scattered over the tongue. Small dark flecks have recently begun to appear caudal to the head on the dorsum where the snake had previously been pure white. The snake is now 2.5 m long and is being maintained in a private collection for breeding purposes.

The examination of skin biopsies failed to reveal any significant abnormalities other than the lack of pigment. Possible etiologies include an acquired or hereditary metabolic defect and idiopathic causes. Nutritional deficiencies are unlikely to be a factor due to the snake being fed whole prey animals. Inflammatory disease involving the basal cell layer which contains the chromatophores could cause pigment loss, but no evidence of inflammation was seen in the skin biopsies. Pope (1965. The Giant Snakes, Alfred A. Knopf, New York) shows a photograph of a leukistic *Python molurus molurus* that is white with dark eyes and no trace of a pattern, but gives no data concerning that snake.

Submitted by **STEVE BARTEN,** 216 W. Tower Drive, Barrington, Illinois 60010, **FREDRIC FRYE,** 741 Plum Lane, Davis, California 95616, **RICHARD EVANS,** Ralston Purina, Checkerboard Square, St. Louis, Missouri 63164 and **PETER IHRKE,** University of California, School of Veterinary Medicine, Davis, California 95616, U.S.A. ●

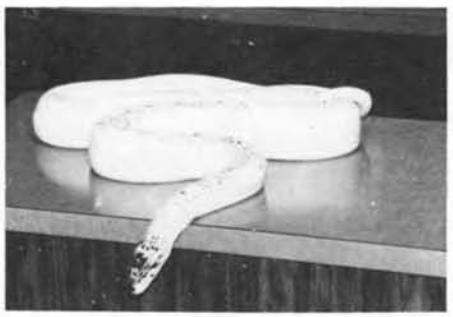

Figure 1. An almost completely leukistic *Python molurus bivittatus.*

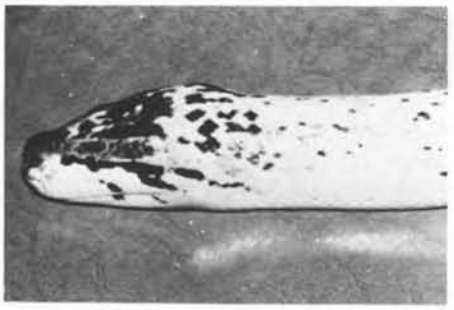

Figure 2. The same snake showing the remaining pigment on the head and neck.

SISTRURUS CATENATUS CATENATUS (Eastern Massasauga). **PATTERN.** An aberrantly patterned *Sistrurus c. catenatus* was captured on 9 July 1979 just north of the mouth of Twelve Mile Bay, Parry Sound District, Ontario, Canada (45° 06' N. Lat., 80° 04' W. Long.). Probably in its second summer, the snake was closely examined but escaped before being sexed and measured. Scutellation appeared normal, however the specimen was atypical in having several dorsal blotches merged together to form longitudinal stripes (Figure 1).

Gloyd (1935. Pap. Mich. Acad. Sci., Arts Lett. 20:661-668 and 1958. Bull. Chi. Acad. Sci. 10(12):185-195) and Nickerson and Mays (1968, Wasmann J. Biol. 26(1):125-131) discuss color and pattern aberrancies in crotalid snakes, including a number of examples of striping in normally blotched species. The first report of a striped example of the genus *Sistrurus* was by Irwin (1979. Herp. Review 10(3):85) who described a striped *S. c. tergeminus* from Kansas. This is the first report of a striped *S. c. catenatus.* Color slides of the specimen have been deposited at the National Museum of Natural Sciences in Ottawa.

Submitted by **MICHAEL J. OLDHAM,** Essex Region Conservation Authority, 360 Fairview Avenue West, Essex, Ontario N8M 1Y6, Canada. ●

ALYTES

INTERNATIONAL JOURNAL OF BATRACHOLOGY

Founded in Paris in 1982, the "Société Batrachologique de France (Société pour l'Etude et la Protection des Amphibiens)" is the first society in the world to be devoted specifically to batrachology. The promoters of the SBF think that, although the study of amphibians has long been included in herpetology, amphibians are only distantly related to reptiles and require a specific discipline, namely batrachology; herpetology should be restricted to the study of reptiles. Membership in the SBF is open worldwide to anyone interested in amphibians.

The SBF publishes the new quarterly journal **Alytes,** which is open to all kinds of papers dealing with the amphibians, their systematics, geographic distribution, biology and protection. The two official languages of the journal are French and English. English abstracts are provided for all papers.

42 authors from 11 countries contributed the 60 papers which were published in the first three volumes of **Alytes** (1982-1984). These papers cover various fields of interest: taxonomy, 19; distribution, 17; conservation, 6; ecology and ecophysiology, 5; behaviour, 3; others, 10. They deal with amphibians of all parts of the world: Europe, 32; Asia, 8; Africa, 4; Australia, 2; America, 1. In these three volumes, 13 new names were proposed: 10 new specific and subspecific names (Anura, 8; Urodela, 2) and 3 new generic and subgeneric names (Anura, 1; Urodela, 2).

Subscription to **Alytes** is independent from membership in the SBF. Subscription rates for volume 4 (1985) and for non-Europeans are as follows:

SBF members	**- Subscription to SBF + ALYTES .....**	**US $ 18**
Non-members	**- Individual subscription to ALYTES .....**	**US $ 12**
	Institutional subscription to ALYTES	**US $ 25**
Extra charge for airmail postage of ALYTES		**US $ 3**

Send orders to Dr. Alain Dubois, General Secretary, Société Batrachologique de France, Laboratoire des Reptiles et Amphibiens, Muséum national d'Histoire naturelle, 25 rue Cuvier, 75005 Paris, France.

Payments should be made in US Dollars by checks (payable to "Société Batrachologique de France") or by credit cards (contact the General Secretary for instructions).

Please contact the General Secretary for any information on the SBF, back issues of **Alytes,** instructions to authors, etc.

TROPIDOCLONION LINEATUM LINEATUM (Northern Lined Snake). **SIZE.** The largest specimen recorded for Illinois was 314 mm in total length (Smith 1961. The Amphibians and Reptiles of Illinois. Ill. Natur. Hist. Surv. Bull. 28, 1-298).

A female specimen was collected near the foundation of a house on South Pasfield Street, Springfield, Sangamon County, Illinois, 8 September 1968. The total length was 432 mm, and the snout-vent length was 378 mm. This exceeds the record for Illinois by 118 mm. With the exception of the large size, the color, pattern, and scale counts are within the accepted range of variation for *T. l. lineatum* (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin).

This specimen was collected by Fred Kincaid, Modesto, Illinois, and is deposited in the herpetology collection of the Zoology Department at the Illinois State Museum, Springfield, Illinois (ISM 622123).

Submitted by **EVERETT D. CASHATT** and **WILLIAM J. WEBB,** Zoology section, Illinois State Museum, Springfield, Illinois 62706, U.S.A. ●

TESTUDINES

CHRYSEMYS PICTA MARGINATA (Midland Painted Turtle). **SIZE.** The largest documented specimen of this subspecies for the Eastern and Central United States had a carapace length of 18.7 cm (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton-Mifflin). The record for the state of Illinois was 16.6 cm (Smith 1961. The Amphibians and Reptiles of Illinois. Ill. Natur. Hist. Surv. Bull. 28, 1-298).

A female specimen was collected while crossing Illinois Route 29, approximately 400 m north of the Springfield city limits near Spring Creek, Sangamon County, Illinois, 27 May 1981, by Ken Pennington of Springfield. The carapace is 19.5 cm (straight-line carapace measurement), therefore, it is the largest recorded specimen for the East and Central United States by 8 mm, and for Illinois by 29 mm. The other measurements are: carapace width, 14.3 cm; plastron length, 17.8 cm; plastron width, 11 cm; shell height, 6.8 cm. Except for the large size, the specimen was within the range of variation for pattern, color and scutation for *C. p. marginata* (Carr 1966. Handbook of Turtles. Cornell Univ. Press). The specimen is deposited in the herpetology collection of the Zoology Department at the Illinois State Museum, Springfield, Illinois (ISM 622398).

CLEMMYS MARMORATA (Western Pond Turtle). **SIZE.** The maximum straight-line carapace length of the Western pond turtle has been noted as 180 mm (Ernst & Barbour 1972. Turtles of the United States) and 178 mm (Stebbins 1966. A Field Guide to Western Reptiles and Amphibians). Herein we report on an unusually large male taken by Denise Brown on 2 July 1984 in the vicinity of Huron, Fresno Co., California. Measurements are: Straight-line carapace length - 182.20 mm, Over the curve carapace length - 179.90 mm, Carapace width @ #8 marginals - 145.80 mm, Plastron length - 154.74 mm, Mass - 854 g.

Of 515 turtles of this species measured by Holland, only a single specimen exceeds this one in size - a female from Klamath Lake, California (CAS 44273), with a straight-line carapace length of 190.80 mm. Of over 450 live animals weighed, this turtle exceeds the previous maximum recorded mass by 40 g. Additionally, this animal has an unusually patterned and colored carapace, bearing a strong resemblance to that seen in old *Chrysemys scripta elegans*. This pattern was noted in less than 1% of the specimens examined, and is present only in large males. This animal is being retained alive in the Roeding Park Zoo reptile collection.

Submitted by **SEAN MCKEOWN,** Roeding Park Zoo, 894 W. Belmont Avenue, Fresno, California 93728 and **DAN C. HOLLAND,** Department of Biology, University of Utah, Salt Lake City, Utah 84112, U.S.A. ●

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

ANURA

ASCAPHUS TRUEI (Tailed Frog). USA: CALIFORNIA: Mendocino Co: 3.2 km (by air) SE confluence of Elder Creek and south fork Eel River on Misery Creek fork of Elder Creek, 610 m, T22 N, R16 W, Sec 34. 6 July 1984. Hartwell H. Welsh, Jr. and Linda LeClaire. Verified by Hartwell H. Welsh, Jr. Redwood Sciences Laboratory (RSL 1029-33). Dark Gulch, 1.2 km N. Albion, Mendocino Co., (MVZ 62214) is the southernmost locality for the species, and Bury (1968, Herpetologica 24:39-46) provided an additional Mendocino Co. record: both are from Redwood forest within 1 km of the coast. The Elder Creek population extends the range 19.2 km east and confirms the presence of the species in the mixed Douglas Fir - hardwood forest. This locality is on the North Coast Forest Preserve of the Nature Conservancy; they are gratefully acknowledged. Contribution No. 30 of the Old-growth Forest Wildlife Habitats Program, USDA Forest Service.

BOOK REVIEWS

The Venomous Snakes of the Near and Middle East, by Ulrich Joger. Ludwig Reichert Verlag, Wiesbaden (West Germany). 1984. 115 pp., 21 line drawings, 20 maps.

This publication, a part of the Tübinger Atlas of the Near East, states its purpose is to summarize contemporary knowledge of the taxonomy and distribution of the venomous snakes of the Near and Middle East. In this, it succeeds admirably. The region covered extends from Turkey, Egypt, and the Arabian peninsula to Pakistan and the southern states of Soviet central Asia. All species of elapids, viperids, and hydrophids are included. *Atractaspis* is considered a colubrid genus; rear-fanged venomous colubrids such as *Psamnophis* and *Malpolon* are omitted. A checklist and key are followed by the major section of the book consisting of accounts dealing with species or occasionally groups of related species. Each account has sections treating taxonomy, diagnostic characters, habitat, and distribution. These represent a critical review of the existing literature plus the author's study of major European collections in an effort to confirm identifications and locality records. Particularly well written and helpful are the sections treating the genus *Vipera* which has undergone extensive evolutionary radiation in this region and *Echis,* the genus of greatest medical importance, whose taxonomy has been in flux for two decades. One need not necessarily subscribe to the author's conclusions, but his reasoning is clear and supported by numerous primary literature references.

There are four appendices that deal with food, reproductive biology, venoms, and antivenins. The author's knowledge of literature on venoms and antivenins is less complete and critical than his knowledge of the taxonomic and zoogeographic literature. There are several errors or misleading statements, e.g. a much too small venom yield for *Naja haje*, failure to list necrosis as a manifestation of cobra envenomation, recommendation of *Deinagkistrodon acutus* and *Calloselasma rhodostoma* antivenins for treatment of bites by *Agkistrodon* of the Middle East. The line drawings of head shields and other features of lepidosis are accurate for the most part, however Figure 7 does not depict correctly the elongate, splinter-like mental of *Enhydrina*. Photographs of the animals and their habitats would have been helpful but would doubtless have increased the cost of publication. The maps are carefully done and show physiographic and ecologic features that influence species distribution. However, they omit political boundaries that, while largely ignored by snakes, are helpful to human users of maps.

But these are trifling objections to an excellent piece of work. Any herpetologist interested in systematics or zoogeography of snakes should have this publication on his shelves. Individuals with a broad interest in regional faunas and medical personnel concerned with snakebite will also find it useful. And I suspect it may well be consulted by a variety of persons with financial or military concerns in this critical and troubled sector of the globe.

SHERMAN A. MINTON
Indiana University School of Medicine
Indianapolis, Indiana 46223, U.S.A.

The Snake's Advocate, by Arthur Carl Stimson. Edited and compiled by Dorothy E. Justman. 1982. 104 pages. 10 photos and 45 figures, soft cover (5½ x 8⅜ in.). $6.95. Eakin Publications, Inc., P.O. Box 23066, Austin, TX 78735.

Arthur Carl Stimson (1892-1968) was a Houston surveyor-civil engineer with an intense interest in snakes and snakebite. He served as lay-consultant to more than 800 snakebite victims from 1948 to 1968. In the 1950s, he was Honorary Curator of Reptiles of the Museum of Natural History of Houston and the Houston Zoo. This snake book has been published by Mrs. Dorothy E. Justman, to preserve her father's notes for posterity.

The larger part of this book is devoted to snake habits and behavior and correcting the folklore and myths surrounding them. The style is colorful and interesting and is written in a popular way typical of books on reptiles written for lay and young readers 40 years ago. I found Stimson's ideas, for the most part, accurate and his style highly entertaining. He deals at length with milk snakes, "hoop" snakes, "charming" by snakes, sea serpents and many other "tall tales." A list of 68 "facts and fiction" was interesting because it indicates the prevalence of myths and lack of general knowledge by the public, at least at that time and region of the country. I was surprised it was necessary to correct the notion that "each and every bone of a snake's body is a poisonous dart."

Three chapters deal with the prevention, first aid and medical management of snakebite. Stimson's ideas reflect the 1927-1955 era in Texas and the work of Dudley Jackson and others of San Antonio. It is unfortunate that excerpts from Stimson's two articles of 1958 and 1960 have been combined with those from other papers by Herbert L. Stahnke and Henry M. Parrish. The average reader, without basic knowledge of the literature, will be left confused and misguided. Although some of these concepts have met the test of time, many others have not and are controversial at best. Stimson's ideas will be of definite value to those interested in the history of snakebite management since, for his time, Stimson was accurate about medical teaching in Texas. To judge his ideas in the light of current knowledge would, of course, be unfair but an introduction to the controversies of that period would have increased the reader's insight as to how far we have and have not come since then. I would have preferred to have found Stimson's original articles reprinted in the book. Although the back cover states, "Premed students will use this book as a basic primer," they would be better off with more current literature.

No credit is given for the figure in the preface, "Texas — Snakebite Case Reports" (Parrish, H. M. 1960. Texas Medicine 60:592-598) nor the year (1958-1959).

Although students of herpetology will find little new in "The Snake's Advocate," I recommend it for pleasurable reading and historical value. Any profit from book sales will be donated to the Reptile House, Houston Zoological Gardens.

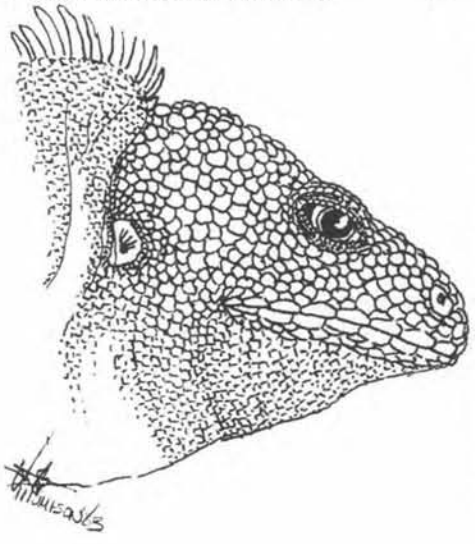
DAVID L. HARDY
5200 East Grand Road
Suite No. 602
Tucson, Arizona 85712, U.S.A.

The Reptiles of British Columbia, by Patrick T. Gregory and R. Wayne Campbell. 1984. Handbook No. 44, British Columbia Provincial Museum, Victoria, British Columbia V8V 1X4. viii + 103 pp., illus. + maps. paper. $3.00.

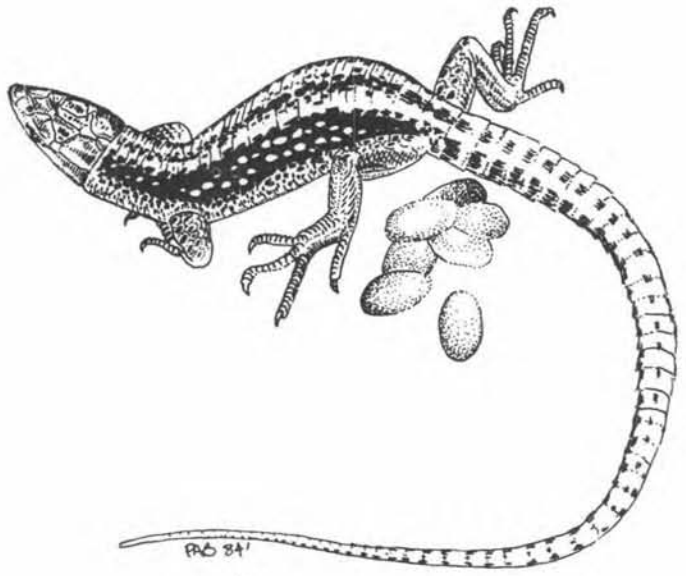
This small (18.3 x 13.2 cm) handbook is the 44th in the fine series of handbooks published by the British Columbia Provincial Museum and dealing with the natural history of Canada's most westerly province. Two other recent publications of this museum also deal with British Columbia herpetology ("A Bibliography of Pacific Northwest Herpetology," by R. Wayne Campbell, et al. 1982, and "The Amphibians of British Columbia," by David M. Green and R. Wayne Campbell 1984). These three volumes are part of a recent resurgence in published books dealing with the Canadian herpetofauna, including "Amphibians of Canada" (Barbara Froom 1982), "The Amphibians and Reptiles of Manitoba" (William B. Preston 1982), "Amphibians and Reptiles of the Pacific Northwest" (Ronald A. Nussbuam et al. 1983), "Introduction to Canadian Amphibians and Reptiles" (Francis R. Cook 1984), and "Amphibians and Reptiles of Nova Scotia" (John Gilhen 1984). It is gratifying to see this interest in Canada's amphibians and reptiles, and I hope it bodes well for the future of Canadian herpetology.

Persons interested in British Columbia herpetology have eagerly awaited the new edition of G. Clifford Carl's THE REPTILES OF BRITISH COLUMBIA (Handbook No. 2, British Columbia Provincial Museum; 1944), which has long been out-of-print. Gregory and Campbell have added substantially to the earlier edition in bringing this work up-to-date. Introductory chapters on Learning more about British Columbia reptiles, Systematics and the use of keys, General biology, and Adaptations to northern environments, preface the main text which deals with the 6 turtle, 3 lizard, and 9 snake species recorded from the province. I was pleased to see more than 3 pages devoted to northern adaptations, an area frequently neglected in studies of the Canadian herpetofauna. There is an introductory section and key for each major group of reptiles (i.e. turtles, lizards, and snakes); for snakes both a field and laboratory key are presented. Useful figures illustrate turtle plate nomenclature, lizard head scutellation, and snake head and body scutellation.

Under each species account are sections on Description, Habits and habitat, Subspecies, Range and distribution, an illustration (drawing), and British Columbia dot distribution map. For some species there are additional headings, such as Feeding and growth, Reproduction, and Mortality, but for other



species these topics are covered under Habits and habitat. The attractive illustrations were provided by Keith Taylor and Brigitta M. VanDerRaay. There is no indication of what type of records the distribution dots are based on. Are they just based on museum specimens, or do they include sight and literature records? Subspecies are not separated by the keys provided, nor are they separately illustrated. When more than one subspecies occurs in the province, it would have been helpful to have separate maps for each subspecies, or at least differentiate between subspecies on the map. For example, three subspecies of *Thamnophis sirtalis* occur in British Columbia, but on the range map provided it is impossible to differentiate between them. Those unfamiliar with British Columbia geography may have trouble finding some of the locations mentioned, as many are not indicated on the introductory map on page viii.



As with some other recent handbooks in the series, THE REPTILES OF BRITISH COLUMBIA contains a number of typographical and other errors which seem to have slipped through the editing process. For example, the distribution map for the Northern Alligator Lizard is labelled *Gerrhonotus coeruleus*, while the text correctly uses *Elgaria coerulea*. Other errors I noticed included the misspelling of *C. m. marmorata* on page 17, postnasal on page 59, *Crotalus* on page 92, *Sceloporus occidentalis* on page 95 and *Phrynosoma douglassi* on page 101.

THE REPTILES OF BRITISH COLUMBIA is aimed at the general public and the interested amateur, and should do much to educate and interest this audience. Readers wishing a more technical and detailed treatment of British Columbia's reptiles would do well to consult Nussbaum, Brodie, and Storm's (1983) book on "Amphibians and Reptiles of the Pacific Northwest" (see review in *Herp. Review* (15(2):44-45).

Despite the minor criticisms mentioned in this review, THE REPTILES OF BRITISH COLUMBIA is an attractive, informative, and well written book which is a welcome addition to the literature on Canada's herpetofauna.

MICHAEL J. OLDHAM
Essex Region Conservation Authority
360 Fairview Avenue West
Essex, Ontario Canada N8M 1Y6

The Turtles of Venezuela, by P.C.H. Pritchard and P. Trebbau. 1984. Society for the Study of Amphibians and Reptiles. i-x, 1-403, 47 pls., 16 maps, 54 figs., Price $45.00, clothbound.

It should first be said that this handsome volume, dedicated to the late and lamented Federico Medem, should be purchased by everyone seriously interested in turtles. The color paintings by Giorgio Voltolina - 25 in all - are glorious, comparable to the best 19th century animal illustrations and are by themselves a reason for owning the book. The text also is packed with fact and opinion to an extent far beyond the promises of the title. In addition, two new taxa are described - a new species *(Phrynops zuliae)* and a new subspecies *(Pseudemys scripta chichiriviche).*

This book is primarily Pritchard's. As is carefully explained, the text's first person singular is always Pritchard, and the book has some of his peculiarities and philosophy. A Spanish edition is hoped for "at a later date" under the senior authorship of Trebbau. The present volume as the second of the series "Contributions to Herpetology" of the SSAR was carefully edited by Kraig Adler and Alan Savitzky and sections of the manuscript were reviewed by a number of colleagues. Publication was sponsored by the Fundación de Internados Rurales (Venezuela).

The inclusion of much more than is strictly relevant to "The Turtles of Venezuela" reflects the lofty aspirations of the authors: "We have, in short, endeavored to produce a book that will go a great deal further than a field guide but which stops short of a holistic review of turtle evolution." Their aim here is a bit beyond their reach; they are well short of the proposed holistic review. However, they can justifiably claim that they have provided more and more various detail than any previous single volume on the systematics of turtles. Most of the detail is referenced, but, as a matter of Pritchard's personal preference, the book also includes statements for which there are no voucher specimens, no statements of sample sizes or many of the other desiderata on which more academic herpetologists tend to insist. Personal observations, data from private collections and the pet trade are utilized without apology — although in the introduction Pritchard's grounds for their use are clearly stated.

In fact, in this group for which museum collections are in general inadequate, Pritchard's procedures are more defensible than in most cases in herpetology — except, perhaps, large snakes, crocodiles or monitor lizards. Turtles have a special problem: they are incompressible and do not fit well in jars. Workers, like myself, who would like to see large series, tend to move on to other groups. (Only John Legler has attempted to solve the problem of large turtle collections.) As Pritchard mentions also, some species are rare or endangered. (I have myself written a paper on a species — *Pseudemydura umbrina* — that I have never seen and that, unless I go to Western Australia — or to Vienna — I can never hope to see.)

The approach the authors have chosen — a hybrid of Pritchard's own Encyclopedia of Turtles and Carr's Handbook of Turtles — is the more readily excused because the book deals with a South American faunal segment. First, only those who work with South American groups know how incomplete our knowledge of that fauna is. Second, political borders are at least as artificial in South America as elsewhere, and context can only be given to a national fauna by going well beyond national boundaries. I do not fault these two authors for going beyond conventional expectations. To do literally "The Turtles of Venezuela" might have produced a relatively unimportant guide book.

The cliche "mine of information" is here wholly justified. There has been a strenuous effort to be up to date, to the extent of frequent citation of "personal communciation" of unpublished data and opinion. The information is, of course, of unequal value, but this is true of all attempts at encyclopedic coverage. There will be lapses in citation but, more important, there are necessarily very great inequalities in the accuracy and gaps in the content of the data summarized — and, of

course, of the summaries — whether or not it has been previously documented in publication.

What follows is a straightforward account of the book's contents. This will best give a sense of the expansive or, some will say, self-indulgent flavor of the book.

There is an introduction that begins with a general description of studies on the South American herpetofauna, then lamenting, quite correctly, that "knowledge of the biology of most South American turtles is very deficient," lauds the few who have contributed to that knowledge. A "Summary" follows, flanked by its Spanish translation: This is little more than a listing of the Venezuelan genera and species. The following chapter shifts the focus to the distribution and zoogeography of all South American turtles. There is a table of the distribution, down to the subspecies, of all the living taxa. The discussion ranges widely; Gondwana, Madagascar, the Antilles and the Galápagos come into the account.

Three pages on shell nomenclature (with a good figure) introduce the systematic sections. Usage is conservative. There follows a key to Venezuelan turtles, flanked again by its Spanish translation. Emphasis is on external morphology, color and size.

The sections on families, genera and species follow a standard format. A diagnosis is given at each level. For families a table of all living and fossil genera is provided. The South American genera in each family are then characterized (with extralimital discussions where appropriate). The synonymy of all extant species in any genus is given in a table (for Venezuelan genera only).

The species chapters all include, in addition to the diagnosis, a description primarily of externals, with in each case a page figure containing three views of the skull (good, but the bones are unlabelled) plus dorsal and ventral views of the shell showing both scute and bone boundaries (the nomenclature in this case was summarized in an earlier section). (These figures are standardized and quite useful.) "Size" is then reported. "Distribution" follows with a map of the total South American range, and "Geographic Variation" also includes the extra-Venezuelan populations of the species. Further sections are on "Habitat," "Feeding," "Reproduction," "Economic Importance" and "Vernacular Names." If there is a "Notes" section, it is concerned with nomenclature.

Following the systematic sections is a 23-page bibliography.

A first appendix gives the locality records. They again include the entire South American range of each species, reporting not only museum specimens but also specimens in private collections, personal communications, Pritchard's own sight records and, for non-Venezuelan localities, literature citations.

A second appendix lists Venezuela's regulations regarding turtles. Sea turtles, *Podocnemis* and tortoises are protected to a greater or lesser degree.

Concluding the book are the plates and maps. Following the 25 superlative color paintings by Voltolina are 22 plates of photographs (166 individual photographs). These are not of the same quality as the paintings, particularly as to color, since the blue tints are slightly exaggerated. Many, however, illustrate points not fully covered in the text. All Venezuelan taxa are illustrated by at least one painting and multiple photographs.

The first of the maps is a color relief map of Venezuela, the second labels states, territories and major localities. The remainder plot Venezuelan records for each taxon, one, two or three taxa to a page.

There is no index.

The practice of citing personal communications and sight records is employed for the two new taxa as well as for earlier known species. The list of type specimens for each of the novelties is less unconventional but still has its peculiarities.

For *Phrynops (Batrachemys) zuliae* the holotype and two paratypes are in the Florida State Museum. One paratype is a skeleton, the other a preserved female without exact locality. Four additional specimens, one still alive, from the type locality — these cited under the rubric "Hypodigm" — are in Pritchard's personal collection. Three additional localities are given on the authority of local informants.

For *Pseudemys scripta chichiriviche* the holotype is in the collections of the Florida State Museum, as is a skeletal paratype. The "Hypodigm" is varied. It includes the MCZ specimen (miscited as 49005 instead of 49055) which was misidentified by me and is the first known specimen of the population and the only juvenile. Two additional preserved specimens are in the collection of the Estación Biologia de Rancho Grande. The remainder are 13 shells and one skeleton in Pritchard's collection and four skulls with jaws in the Rancho Grande collection.

It is clearly unfortunate that a subspecies based partly on color should have only four preserved specimens out of a type series of 24. More specimens were indeed seen: an undetermined number of live specimens were released in a park pool — at least 14. Some of these are apparently those showing ventral pattern variation in Plate 38A. It is incidentally to be noted that Pritchard mentions (legend to Plate 36D) that a specimen from Maracaibo of *P. s. callirostris* "may exhibit a degree of intergradation" with *P. s. chichiriviche*.

It is no flattery of any taxonomic publication to say that it will be frequently reread and cited in the future. There are, however, degrees of value. This volume — despite occasional caveats and hesitations, which will differ with each reader — belongs among the worthy, those that will be consulted because of quality, not despite it.

I acclaim the intention of the authors to make the relevant turtle literature known to South American readers. The latter will justly claim that much of that literature is still not readily accessible to them. The authors have, however, made a great deal of that information available in short compass and clarified much. This is another kilometer stone in the knowledge of the South American herpetofauna.

With regard to Pritchard's use of unconventional data and material, this reviewer has mixed feelings. I sympathize with the effort to get on the record all information and recognize, as I have said above, that the problem is greater for turtles than for most other groups. However, as regards the pet trade and private collections, I have a mostly negative viewpoint. To overmuch rely on anonymous pet trade data is to appear to acquiesce in a traffic that unquestionably has its very dark side. In the matter of private collections, it is not the greediness of large institutions alone that makes them denigrate individual and impermanent collections, it is also recognition of the danger (and often the fact) of the loss or diminished value of material of genuine scientific importance when there exists neither the staff nor the tradition that can ensure its safety nor its availability to the scientific community in general. And, in the matter of documentation, I will always favor more, rather than less, detail about specific specimens to *ex cathedra* generalization. But this would have made the book longer and more expensive. As it is, it is a bargain.

ERNEST E. WILLIAMS
Museum of Comparative Zoology
Harvard University
Cambridge, Massachusetts 02138, U.S.A. ●

The Turtles of Venezuela, by Peter C. H. Pritchard and Pedro Trebbau. 1984. Society for the Study of Amphibians and Reptiles. i-x, 1-403, 47 pls., 16 maps, 54 figs., Price $45.00, clothbound.

The herpetofauna of South America presents an interesting mix of archaic and derived groups that mirror a complex geological and biological history. The appearance of *The Turtles of Venezuela*, by Peter Pritchard and Pedro Trebbau, provides a detailed treatment of a part of this fauna. With the support of the Fundación de Internados Rurales, this attractively bound edition, including 25 outstanding paintings (by Giorgio Volatino), is available at a reasonable price. The book is printed entirely on acid free paper ensuring the long life of each copy and is sturdily bound in the colors of the Venezuelan flag (yellow, blue and red).

From a physical standpoint, the book is phenomenally well produced. The plates and the Venezuelan distribution maps are outstanding, and worth the price of the book by themselves. The Venezuelan base map does not include many place-names mentioned in the text. Readers unfamiliar with Venezuelan geography will find it useful to read with a more detailed map in hand. The unlabeled text figures are better than average. I only found two figures that were in error and in both cases sutures (Fig. 38) or sulci (Fig. 12) were omitted. Most of the illustrated shell and skull material came from the senior author's personal collection. I prefer that illustrated material be from established collections, so that other students of turtles could have easier access. There is no statement concerning the eventual fate of the senior author's collection. Thus, future students may not be able to locate the material illustrated by these authors. The text is clear, well laid out and I found no typos. Judging from the editor's note on inside front cover, which lists the numerous reviewers, this volume has been

subjected to close scrutiny.

The book is arranged by family groups, preceded by an Introduction, Summary and Keys (in both Spanish and English), and chapters on Distribution and Zoogeography, and Shell Nomenclature. After all the taxa have been discussed, there are two appendices (Localities and Conservation Regulations), a Literature Cited section, the superlative color plates, and the Venezuelan distribution maps. Each family chapter begins with a summary of the entire family including a "diagnosis" (often characterizations that rely mostly on external features, rather than true diagnoses), a tabular list of the genera recognized by the authors (but not necessarily of wide acceptance), a brief discussion of the South American genera, and occasionally a section on some miscellaneous subject (e.g. "Evolution of Terrestriality Among Turtles" p. 202; "Extinct Families of Sea Turtles" p. 275). These miscellaneous sections are simplified summaries of complex issues in turtle biology. Following the "family" chapters, there are separate chapters for each species. Included in each of these chapters is a synonymy, a diagnosis, a description, comments on size and growth, distribution, geographic variation, habitat, feeding, reproduction, economic importance, vernacular names, and where necessary nomenclature notes or an etymology section. The authors describe two new taxa: *Phrynops zuliae* (on page 135) and *Pseudemys scripta chichiriviche* (on page 191). Their use of paratypes and of the hypodigm concept of Simpson (1961) is likely to cause confusion. Are specimens from the hypodigm part of the type series? From Simpson's definition of the hypodigm concept, I would have to say yes. However, strict application of the ICZN rules would exclude Pritchard & Trebbau's hypodigm from the type series — in direct contradiction of Simpson's original intention for the hypodigm concept.

Pritchard & Trebbau (1984) is a long book considering that its title portends only a treatment of the turtle fauna of Venezuela. However, this title understates the intention of the book which goes far beyond a simple survey of what is known of the natural history of the 24 Venezuelan turtle species. A good attempt has been made to collate and summarize all information that might be pertinent to these 24 species, even if this information comes from populations outside Venezuela. A great deal of information has been included that has very little to do with Venezuelan turtles and the authors provide a justification for adopting this practice throughout the text. Thus, there are discussions of Galápagos tortoises and of meiolaniids, in the introductory zoogeography chapter. These discussions would be better if the interpretation or analysis was original or if earlier work was critiqued.

The authors have produced a volume intended for specialists, and it must be judged by the standards applied to monographic works. Certainly, some of these standards are demanding and the authors contend that these standards would inhibit the free flow of information, especially regarding locality data. Consequently, Pritchard & Trebbau have chosen to accept locality records that many zoologists would exclude. Of course, many of their records may be valid, but it will be impossible for future students to independently verify their information, since it relies on heresay and interpretation.

The "Distribution and Zoogeography" chapter is old fashioned and is a description, not an analysis. The results of Holden & Dietz (1972) were misquoted, when the age of the Galápagos was discussed. Pritchard & Trebbau (1984) said that Holden & Dietz showed that the Galápagos Islands originated about 40 mybp. Holden & Dietz showed that the Galápagos rift, which they believe created the Cocos plate, originated 40 mybp.

Pritchard & Trebbau sometimes cite inappropriate papers to support their contentions. For example, they cite Pritchard (1979) as support for the position that *Geochelone elephantopus becki* is one of the most variable races of Galápagos tortoises. However, this citation does not provide detailed enough information on variability. The authors employ the same strategy when elevating *Rhinoclemmys punctularia diademata* to specific rank. Sometimes citations are absent where they should have been included. For example, the diagnosis of the Testudinidae is an almost verbatim repeat of the diagnosis of Loveridge & Williams (1957), but no citation is provided.

Pritchard & Trebbau are not shy about speculating with very little data. Weakly substantiated hypotheses include: a model for the origin of the hinge in *Pelusios*; a functional explanation for the appearance of hexagonal neural bones (p. 166); adaptive scenarios for certain peculiarities of tortoises (p. 200-201); flat-topped carapaces for tortoises so they can wedge their bodies between saplings (p. 216); and the dispersal of *Kinosternon scorpioides* by bird transport (p. 243-244).

Occasionally, Pritchard & Trebbau make a statement whose significance they do not discuss, but whose implications are far reaching. For example, they refer to the postorbital bone of a testudinid as the postfrontal (p. 210). The only known turtle that may have a postfrontal is *Proganochelys* (see Gaffney 1979).

It would have been nice if the authors had included a list of specimens they had personally examined and measured; and there is no statement about how shell measurements were taken (i.e. curved or straight carapace length).

Other nit-picks come to mind, but over-all the book is a success. Its fact-filled pages, excellent illustrations, and reasonable price make it a good buy. Most herpetologists will benefit from having it.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

1985 JOINT ANNUAL MEETING
SOCIETY FOR THE STUDY OF THE AMPHIBIANS AND REPTILES
28th Annual Meeting
HERPETOLOGISTS' LEAGUE
33rd Annual Meeting
UNIVERSITY OF SOUTH FLORIDA TAMPA, FLORIDA
4-9 August 1985

DISTINGUISHED HERPETOLOGIST LECTURE
Carl Gans, The University of Michigan, Immediate Past President of SSAR, will present the HL Distinguished Herpetologist Lecture.

TECHNICAL PAPER PRESENTATIONS
Research reports will be given in two formats: oral presentations (with several concurrent sessions) and poster sessions.

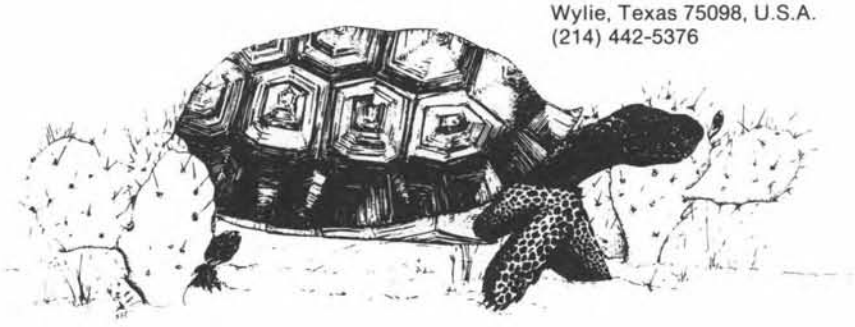
SPECIAL HERPETOLOGICAL EVENTS
1. Florida Focus: National Diversity and Progress: Amphibians and Reptiles in Florida. Steven P. Christman.
2. Herpetology Exam: test your knowledge of the field of herpetology. Coordinated by Marty Crump. (SSAR)
3. Herpetologists, Past and Present: an updated version of the very popular slide show prepared by D. Dennis and J. E. Juterbock. (SSAR)
4. Busch Gardens Zoological tour.
5. Special closing night dinner featuring alligator and turtle sauce piquant, coordinated by Ernie Liner.
6. 9th Annual Conference of the Regional Herpetological Societies.

SOCIAL EVENTS
1. Sunday night social with local entertainment.
2. Monday night bar-b-que at the Museum of Science and Industry.
3. Wednesday night auction and social. (SSAR) Saleable items, *particularly herpetological mementos,* are being actively solicited for the auction. Please forward same to Henry R. Mushinsky or bring them to the meeting.

DISPLAYS AND WORKSHOPS
1. Workshop on the status of *Gopherus* spp. coordinated by Richard Franz and Ren Loehefner.
2. Live amphibians and reptiles of Florida, organized by Paul Moler.
3. Numerous artists and exhibitors will be displaying their work, coordinated by Ruth Zantzinger.

FIELD TRIP
An all day field trip is scheduled to Archbold Biological Station. Glen Woolfenden will be the guide.

ADDITIONAL INFORMATION
A detailed Program and Call for Papers will be mailed separately. For further details write or call Henry R. Mushinsky, Biology Department, University of South Florida, Tampa, Florida 33620, U.S.A. (813-974-2878).



All interested persons are welcome to attend. ●

SSAR REGIONAL HERPETOLOGICAL SOCIETY 9TH ANNUAL CONFERENCE, TAMPA, FLORIDA

The Ninth Annual Conference of the Regional Herpetological Societies will be held during the 1985 joint meeting of the SSAR and HL at the University of South Florida in Tampa, 4-9 August. The title of the conference is "Methods to Enhance the Regional Herpetological Society." Tentative topics are: improving newsletters and journals; personal relations; preparing slide programs; auctions; mall shows; and membership involvement.

There will also be tables available for Regional Societies to distribute information about their society. Each society should provide approximately 100 brochures to be distributed at the conference. The brochure should include purpose, history, activities, membership categories, dues, and contact person for additional information.

Inquiries may be directed to:
Terry Hibbitts, Chairman
Regional Herpetological Society
Liaison Committee
309 South 4th
Wylie, Texas 75098, U.S.A.
(214) 442-5376 ●

SSAR BUSINESS

SSAR ELECTION RESULTS

The results of the 1984 SSAR Election are as follows:

President-elect: Sherman Minton
Secretary: James S. Jacob
Treasurer: Henri Seibert
Board - Regular: Harold Dundee
Board - Regional Societies: John Behler

The Society extends its gratitude to the Nominating Committee (Diane M. Secoy, Chair) and to the SSAR Elector (Darrel Frost) for their hard work, and to the outgoing President and Board Members for their service during their terms. ●

LETTER FROM THE PRESIDENT

Dear Member:

I am writing this letter in the hope that it, and perhaps subsequent ones, will stimulate increased exchange between you, the body of our Society, and those whom you have elected to run SSAR on a day-to-day basis. Presently, I feel that few members give much thought to what SSAR does or could do, preferring to trust in the decisions of the elected Board. This is not bad and indeed is how our entire country is run, but I was frankly stunned upon becoming President to note how small a percent of our membership actually voted in the 1985 election — less than 25%. I expected a far greater return for a mail ballot to a rather cohesive group.

SSAR's success has been linked to its innovativeness, and that in turn has come from its membership as actual ideas and as financial support for programs and publications. Some new ideas have blossomed into very successful entities: *Facsimile Reprints* and the Grants-in-Herpetology program. Others have had rough going: last June *Recent Herpetological Literature* lost the entire free computer resource which was so crucial to its success; no alternative free sources are available and while *RHL* is not certified dead, it is certainly on the critical list.

Is SSAR measuring up to the expectations you had when you sent in your dues (you have sent them, haven't you)? If not, I'd like to know since if common patterns surface the Board can address them. Do you use all of the benefits of your current membership (the *Journal, Herp. Review,* voting rights, publications discounts, etc.)? Would you, or friends and associates, like to see us initiate a new class of membership costing less and receiving fewer benefits? Do our Annual Meetings sponsor the activities of greatest interest to you? What do you like most and also least about them?

I close this letter by asking your continued support of SSAR. Try to build the Society by encouraging prospective members to join. Dues go to support all the valuable features of the Society. Grants-in-Herpetology depends heavily on private contributions for its growth. Do you know of businesses which donate to non-profit organizations? Participate in running your Society by corresponding with officers and/or attending the Business Meeting at the Annual Meeting.

Thanks, and I look forward to hearing from you.

Sincerely,
George Pisani ●

LEFT TO RIGHT: Professor Kuang Yang Lue, Professor Kraig Adler, and Professor Ermi Zhao.

HERPETOLOGY OF CHINA PRESENTED AT 1984 SSAR MEETING

Herpetologists in attendance at the 1984 SSAR meeting at the University of Oklahoma were given the unique opportunity to view slides of many amphibians and reptiles native to China and learn about some aspects of their biology. Professor Ermi Zhao (Chengdu Institute of Biology, Chengdu, Sichuan, China) and Professor Kuang Yang Lue (National Taiwan Normal University, Taipei, Taiwan, China) presented special lectures on the amphibians and reptiles of China. A great deal of new information about the habitats and ecology of many rarely seen animals was provided to a large, appreciative audience. Professor Kraig Adler (Cornell University) arranged and moderated the special session. ●

LATE FEE FOR MEMBERSHIPS TO START SOON

Late renewals of SSAR memberships are very costly to the Society. Postage to send back copies of publications is in itself considerable since they cannot be mailed at bulk rate. In view of this, a $5.00 fee will be levied on all late renewals after 1 June 1985. This date will change to 1 April in 1986 and thereafter. ●

SSAR TRANSLATIONS PROJECT

The object of this project is to make available to SSAR members accurate translations of foreign language research articles. Since SSAR has not budgeted money for translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy (or reprint) of the original and the translation to the editor. A few people have volunteered to translate articles and we are interested in hearing from any others who are willing to contribute their time.

If you have an article for translation that you feel would appeal to a large segment of the herpetological community, send a copy or reprint to the editor and we will try to have it translated.

We now have a total of 68 translations available through the Translations Project. The titles of 34 are listed below. Previous titles appeared in *Herpetological Review* 10(3):82-83, 1979; and 13(4):111-112, 1982. Copies of these are available (.06/page) through the Translations Project Editor, Robert D. Aldridge, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103, U.S.A.

OVERSEAS PUBLICATION EXCHANGE PROGRAM

The Society has a program which can coordinate the exchange of SSAR memberships, journals, and other herpetological publications between Society members and scientists in countries that face difficulties with exchange of foreign currency. This program provides an opportunity for herpetologists in these countries to receive an SSAR membership in return for publications (an arrangement which is best worked out between participating individuals). We encourage your participation in this program. Interested members should contact our Treasurer, Dr. Henri C. Seibert. ●

ERRATUM

The photograph below was inadvertently omitted from the article "Aggression Between Two *Drymarchon corais melanurus* in Campeche, Mexico" by Robert B. Waide and Richard Thomas, which appeared on page 10 of the March 1984 issue of *HR*. The photograph demonstrates the severity of the aggressive encounter between the two snakes. The editor apologizes to the authors for this omission.

●

SSAR CONTRIBUTORS

Once again it is our pleasure to acknowledge our Sustaining and Contributing Members and those who have donated to Grants-in-Herpetology Fund for the year 1984. Although individual contributions may not have been large, the sum total was $1586, a not insignificant part of the SSAR budget.

LETTERS TO THE EDITOR

EDITOR:

We write this unsolicited review (*A Synopsis of the Class Reptilia in Australia* by Richard W. Wells and C. Ross Wellington. Australian Journal of Herpetology 1 (3-4):73-129) because of our deep concern of the possible effects that this publication might have, both on the status of taxonomy in Australia, and on our understanding of Australia's reptilian fauna in general. Being past members of the editorial board of this journal we feel that it is our responsibility to alert the herpetological community to the history of this publication and to the means by which it was published.

First, it should be noted that the authors R. W. Wells and C. R. Wellington (the managing editor and advertising sales manager respectively [front cover]), own and publish this journal themselves. Second, this paper was not submitted for review to any of the three members of the editorial board (Prof. H. Heatwole and Dr. J. Miller, University of New

Wildlife Publications, Inc. / 904-378-7944
1014 NW 14th Avenue, Gainesville FL 32601 USA

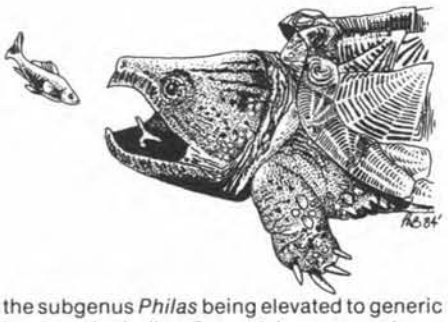
England, N.S.W., and Dr. M. King, Australian National University, A.C.T.). Third, all manuscripts which had been refereed and accepted by the editorial board and which were to be published in order of receipt were set to one side by Wells and Wellington so that their unrefereed manuscript would be published with first priority. In fact, to our knowledge no paper processed by the editorial board has been published and distributed. Fourth, because of the actions taken by the authors in overriding the function of the editorial board and in manipulating the order of publication to their own advantage, the three members of the editorial board resigned. As a result, the statement which appears on page 129 of this publication "Accepted: 20 December, 1983," is misleading and should not be interpreted as meaning accepted by the editorial board.

The seriousness with which the Australian herpetological community regards this publication may be gathered from a resolution adopted at the annual general meeting of the Australian Society of Herpetologists. A unanimous vote declared that the above mentioned society would lodge an appeal with The International Commission on Zoological Nomenclature for the suppression of this article.

It is clear to us that this opinion results from the very poor quality of the article. This major revision of Australian reptiles suffers from a series of substantial taxonomic mistakes which include the following:

1. Fundamental omissions and duplications of species listed.
2. Significant errors in taxonomic procedure.
3. Subdivision of species on imprecise and unspecified criteria.
4. Allocation of species to genera without describing diagnostic characteristics.
5. Use of nomenclature which trivializes taxonomy and herpetology.

To substantiate these allegations we do not intend to list all of the numerous mistakes found in this synopsis; space and time prevent this. The families Gekkonidae and Varanidae provide an adequate source of examples, although more blatant instances will be drawn from other areas.



The careless compilation of this synopsis is highlighted by both duplication and omission of recognized species. Thus, in the Agamidae we see *Amphibolurus reticulatus* (Gray 1845) listed as *Ctenophorus reticulatus* (Gray 1845), and also placed in a new genus *Licentia*, where it is both listed as *reticulatus* and *Licentia reticulata* (Gray 1845). One has to go no further than *Gehyra minuta* King 1982, in the Gekkonidae, and *Tropidechis carinatus* (Krefft 1863), in the Elapidae to find examples of omission.

There are numerous errors in taxonomic procedure. Subspecies in all reptilian families are elevated to specific status without any form of justification; they are simply listed. Clearly, the authors who initially described the many subspecies didn't think that they deserved full species status, presumably because they could find no consistent distinguishing characteristics. Species from the Gekkonidae which have been elevated in this manner include *Crenadactylus naso, Crenadactylus rostralis, Nephrurus cinctus, Nephrurus occidentalis, Nephrurus pilbarensis, Pseudothecadactylus cavaticus.* More disturbing are the numerous populations of species which have been given formal species status on a regional basis, and again without any morphological characteristic demarcating them. Thus, *Phyllodactylus marmoratus* (now *Christinus*) is subdivided into eastern and western forms (one as yet unnamed). *Cyrtodactylus tuberculatus* is resurrected and confined to Cape York. *Diplodactylus furcosus* is resurrected to accommodate "the distinctive eastern form of the *D. vittatus* complex" even though there are two eastern forms (King 1977). *Diplodactylus hillii* is resurrected from *D. conspicillatus* and confined to the Torresian subregion of the N.T. Here too the list appears endless, and in the Gekkonidae populations which have been given specific status include *Heteronotia anomalus, Heteronotia australis, Heteronotia derbianus, Nactus eboracensis, Diplodactylus platyurus, Oedura cincta, Strophorus aberrans, Underwoodisaurus husbandi* and *Dactylopertus grayi.* All of these names have been resurrected to cover specimens in broad geographic areas, and not a single diagnostic character is described. The danger of this approach is seen with *Dactyloperus grayi* (Steindachner 1867); here the eastern populations of *Gehyra variegata* (small gekkos with a snout vent length never greater than 57 mm) have been grouped under a holotype which has a snout vent length of 65 mm and overall length of 132 mm, and appears to be a member of the *G. australis* species complex on all its external characteristics. More damning is the fact that *D. grayi* has been placed in a separate genus to *Gehyra australis.*

The case of *Gehyra grayi* highlights the scattergun approach to generic divisions made by the authors. Genera have been resurrected without any explanation as to what characters should be used to categorize species allocated to them. The genus *Gehyra* Gray 1834 has been split into four *Gehyra* species and thirteen *Dactyloporus.* No reasons or characteristics are given. On closer examination the groupings are completely unsupportable. One of the species, *Gehyra pamela*, recently separated from *Gehyra australis*, its sister species, by a series of subtle morphological differences has now been placed in a separate genus.

In the Varanidae, subgenera are similarly elevated to generic status without explanation. Thus, *Odatria* is now a genus and *Pantherosaurus* Fitzinger 1843 has been resurrected, and a group of species previously in the subgenus *Varanus* are included in this. For some unknown and unexplained reason, *V. glebopalma* has made the transition from *Odatria* to *Phantherosaurus.* Moreover, *Varanus timorensis scalaris* and *V. timorensis similis* were "formally elevated to species status," however, Storr (1980) had already restricted the Australian form to *V. timorensis scalaris* because of inconsistency in diagnostic characteristics for *V. timorensis similis.* A new genus *Worrellisaurus* was created, the description of this is so general as to include most small varanids of diverse groupings.

As one might by now have expected, the two Australian crocodilians have been placed in separate genera; *Crocodylus* and *Philas*,

the subgenus *Philas* being elevated to generic level and including *Crocodylus novaeguineae* and *C. johnstoni*, whereas, *porosus* remains in *Crocodylus.* Once again, no grounds are given for the distinction between these genera even though these crocodiles are acknowledged on morphometrics, electrophoretic similarities, microcomplement fixation, and chromosomal grounds as being very closely related forms (Densmore 1982; Cohen and Gans 1970).

The trivialization of the science of taxonomy is not only illustrated by the wholesale and reckless nature of the changes made by Wells and Wellington, but is reinforced by their pointed choice of names:

Licentia gen. nov.
"Etymology: Licentia means 'freedom to do as one pleases'."
Phthanodon gen. nov.
"Etymology: Phthanodon means 'to anticipate' or 'do first'."
Anepischetos gen. nov.
"Etymology: Anepischetos means 'unrestrained' and alludes to the 'ideal intellectual state'."
Solvonemesis gen. nov.
"Etymology: Solvonemesis means to set free the goddess of retributive justice."
Vaderscincus gen. nov.
"Etymology: named for Mr. Darth Vader."

The authors tell us that their publication should be seen "not as anarchistic taxonomic vandalism, but as a decisive step intended to stir others into action." In our opinion, the reverse of this statement is true.

EDITOR:

The recent and unfortunate publication of "A Synopsis of the Class Reptilia in Australia" by R. W. Wells and C. R. Wellington in the Australian Journal of Herpetology (Vol. 1, pp. 73-129) requires additional comment. Max King and Jeffrey Miller have reviewed this article and pointed out some of the features of it which are to be deplored. Inasmuch as this article has received widespread disapproval by the Australian herpetological community, and various Australian herpetologists feel that their professionalism has been compromised by this article, some clarification regarding the status and affiliation of the Australian Journal of Herpetology is desirable. The Managing Editor and the Advertising Sales Manager for the journal publish and distribute the journal themselves. Although the address listed in the cover of the journal might imply that the journal has some official connection with the University of New England, such is not the case. During the time Mr. Wells was a 1st year biology student at the University of New England, the Department of Zoology provided him with a postal box for the receipt of manuscripts and correspondence relating to the journal. He did not complete that year of study (and has not furthered his formal training in biology since) and that postal privilege lapsed. He then moved to Sydney but for some reason rented a postal box at the University branch of the local post office to handle journal correspondence. All mail received at that address was merely forwarded to Sydney and had no official connection with the University of New England. Any person can rent such a post office box. Although the University of New England has never had any official connection with the journal, two staff members (H. Heatwole and J. Miller) had urged that manuscripts for the journal be reviewed before publication and offered to be members of an Editorial Board to process such reviews. A number of manuscripts were received by members of the Editorial Board and were sent out to referees, edited, and returned to Mr. Wells. None of the papers which went through this process has ever been published, or if so, they have not been distributed. Attempts to ascertain the status of those papers has been unsuccessful. As a consequence of the dissatisfaction the Editorial Board felt with the handling of the journal, all three members resigned. The purpose of this brief note is twofold:

(1) To indicate the lack of any official connection of the University of New England with the Australian Journal of Herpetology, and

(2) To indicate to those herpetologists from various countries whose papers went through the reviewing process, that the status of their publications are now uncertain and that they may wish to make other plans for their manuscripts.

Finally, I would like to point out that despite the similarity in names, The Australian Journal of Herpetology has no connection at all with the Australian Society of Herpetologists.

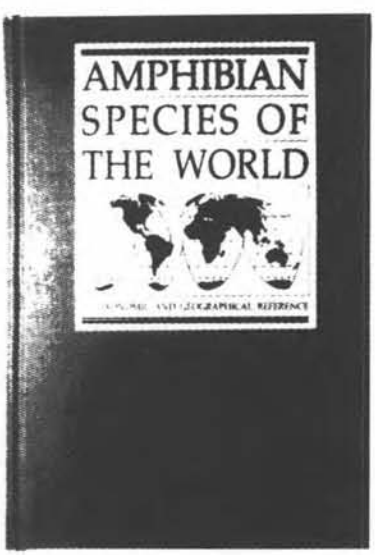
COMMENT ON TWO CHECKLISTS

EDITOR:



Perhaps it is the advent of computers that has recently provided us with an increasing number of checklists which deal with portions of the reptilian and amphibian fauna of the world. The need and opportunity to summarize a portion of our knowledge has led to the development of some very large projects. I here use the advent of two recent checklists of the Australian herpetofauna as an opportunity to evaluate the purposes of checklists and to note some problems that they may generate.

Checklists are presumably mechanisms of organizing information. Taxonomic checklists then provide us with the list of currently recognized units, an overview of forms that belong to a group or occur in a region. Presumably, they are designed to aid those working with the material or in the region; their

value then depends on the utility to the user community.

Whereas checklists were once documents of interest to a limited number of the cognoscenti or to those amateurs and professionals interested in a particular group, they now serve as a basis for legislation and environmental decisions, changing their usage and potentially their legal status. This makes it ever more important that their nature be defined. To what extent is a particular list documented by systematic review, i.e. does it represent an individual or a consensus opinion? To what extent does it represent undocumented opinions which have not previously appeared in the reviewed literature? The new pattern of usage makes it obviously desirable that checklists include statements giving the bases for inclusion and omission and that these be documented by reference to the primary literature and to reviews therein.

The difficulties generated when much unpublished material was included in a checklist were documented by the Sixth edition of the Check List of North American Amphibians and Reptiles (Schmidt 1953). This included many name changes deriving from the author's extensive information of work in progress in numerous institutions. Unfortunately, much of the work accepted in the list ultimately remained unpublished and other aspects included therein were not accepted by the community. More important is that the basis of Dr. Schmidt's vast knowledge of herpetology was not documented, so that the list soon became a historical document of little practical value.

Perhaps the greatest difficulty likely to be encountered in checklists reflects the temptation to make major taxonomic decisions in this format. A shorthand presentation is then possible and the extensive documentation otherwise deemed desirable seems to be obviated. The International Rules of Zoological Nomenclature have established minimum standards for the publication and acceptance of names and name changes. However, the standards there prescribed are indeed minimal and additional information (diagnosis, range of the new taxon, other specimens available, comparative basis) is certainly desirable. This amplification belongs in a separate place distinct from a checklist. It may be that the next revision of the International Rules should take this into account.

In this frame, ideal checklists should list the primary names and the synonyms with information about type locality (best in "original spelling"), the types (including numbers and information, whether they were indeed re-examined recently), the authors who provided revisions, and a distribution documented by literature references and occasionally by mention of museum specimens (with number). Finally there should be clear citation of the source of all information referred to, at least to the last revision, and information about its scope. The assemblage of such information presents a useful aid to colleagues. However, although preparation of a checklist may involve a tremendous effort, it should not be mistaken for an original, creative project. Indeed, the magnitude of the creative component is likely to be correlated with the magnitude of error and hence of uncertainty. In contrast, reviews and revisions likely represent sources of original information. Their authors are likely to contribute much more to our understanding than those who merely generate new names. As checklists are entirely derivative documents, rules should be developed discouraging copyright protection for them, even though this allows an occasional republication with little more than a change of the original "authorship" (cf. Gans 1966; Murthy 1974).

Two checklists at hand offer a useful contrast within this framework. Cogger's checklist of the amphibians and reptiles of Australia (Cogger et al. 1983) can presumably be faulted for appearing quite late. Many of the nomenclatorial assignments there documented have long been available in his monumental "Reptiles and Amphibians of Australia," a volume which appeared eight years earlier and is now in its third edition (Cogger 1975, 1983).

The second checklist was apparently published by the editors of the journal in which it appears. It claims to be derivative of the former list and in a way provides a commentary thereupon. However, it introduces many new generic and specific designations, all with adequate but minimal documentation, for instance lacking diagnoses rather than descriptions. Some of the new names are patronymics, recognizing herpetologists and friends of the authors; other names refer to odd words of no obvious connection to the attributes of the organisms (note *Eroticoscincus*) and one celebrates Darth Vader (see King and Miller this issue). There is at least a faint suspicion that a number of the taxa here added are subjects of revisionary efforts by other specialists (some of whom may have been less than diligent in rushing their conclusions to the press). The list provides further comments indicating that its authors consider many yet-unnamed additional forms worthy of specific distinction. The basis of these decisions seems often to be geographic; i.e. forms occupying ecologically discrete regions should be considered distinct.

News items in the local press (e.g. Illiwara Mercury, 11 May 1984; Blue Mountain Gazette, 23 May 1984; Sydney Morning Herald, 20 October 1984) suggest that Wellington and Wells published the checklist to document their objection to practices of the Australian Museum (at which Dr. Cogger is the Associate Director). These authors also seem to have noted that they described these forms to document that these names had for too long been kept unpublished by other workers, thus precluding protection of the forms. Such a set of claims by itself is likely to hinder rather than help the understanding of the Australian herpetofauna.

The unfortunate thing is that all of the individually questionable practices have occurred before and indeed some in the publications of highly "respectable" systematists. In the present document, we see a regrettable assembly of gestures ranging from the tasteless, to the legal but inappropriate. The names proposed clearly have legal status. However, it may well be good to use them with caution as a number of individuals are apparently preparing a petition asking the International Commission to take action on this case.

It seems that suppression of this and similar projects under the plenary powers would be a highly appropriate action. At the very least, this affair raises some disturbing questions whether the rules governing the process of taxonomic study in the last century are adequate for circumstances likely to arise in the age of electronic word processing. Unless, the International Commission for Zoological Nomenclature chooses to come to grips with this series of issues, we may face a return to the pattern of the early Nineteenth Century, with individual taxonomists able to decide which names they chose to recognize. The resulting chaos is hardly likely to facilitate biological research.

NEWSNOTES

ZIMBABWE HERPETOLOGISTS SEEK EXCHANGE

A group of about 20 individuals in Zimbabwe has been meeting for the past four years to share their herpetological interests, which mostly concern snakes. This group is interested in obtaining films and publications concerning American reptiles but is unable to send currency out of the country. Individuals interested in establishing an exchange program are invited to contact:

Mr. Ben Vermeulen
P.O. Box 797
Harare
Zimbabwe ●

SECOND CARIBBEAN GREEN TURTLE TAGGING TRIP

The New York Zoological Society will sponsor its second green turtle tagging trip at Tortuguero, Costa Rica, during July, August and September 1985. This program augments and supports on-going sea turtle research sponsored by the Caribbean Conservation Corporation. Teams will be escorted by a NYZS staff person and will be supervised by a core staff of CCC personnel.

Additional information and applications are available from:

John Behler
Curator, Department of Herpetology
New York Zoological Society
Bronx Zoo
Bronx, New York 10460, U.S.A. ●

HERPETOLOGISTS' LEAGUE— HONORARY MEMBERS

The Herpetologists' League invites recommendations of "recognized leaders in the field of herpetology" to be considered for nomination as Honorary Members. Names of individuals recommended, *accompanied by supporting documentation,* must be received by 1 July 1985. The Executive Council will review the recommendations and present a slate of nominees to Members present at the General Business Meeting, during the Annual Meeting at the University of South Florida, 4-9 August 1985. Names should be submitted to:

C. J. McCoy
Vice-President *(HL)*
Carnegie Museum of Natural History
4400 Forbes Avenue
Pittsburgh, Pennsylvania 15213, U.S.A. ●

WORKSHOP ON LARVAL AMPHIBIAN BIOLOGY

An intensive one-week workshop on larval amphibians will be offered at the Highlands Biological Station June 3-7, 1985. Topics to be covered include systematics, morphology, behavior, physiology, and ecology of frog tadpoles and salamander larvae. Primary emphasis will be on the identification, gross morphology, behavior, and ecology of these organisms. The course will include lectures, laboratory studies, and field investigations. Credit (2 semester hours) is available through either Western Carolina University or the University of North Carolina at Chapel Hill. Instructors: Richard J. Wassersug, Dalhousie University and Richard C. Bruce, Western Carolina University.

The Highlands Biological Station is located in the southern Blue Ridge Mountains, within an area of high amphibian diversity. The Station provides superb laboratory and field facilities for instruction and research, and comfortable living accommodations for students and visiting researchers.

Costs — Tuition: $100; Housing Fee: $20.

University Credit (workshop may be taken without credit) — Western Carolina University: $40 registration fee, $15 application fee. UNC-Chapel Hill: $50 registration fee.

For further information and application forms contact:

TORTOISE INFORMATION SOUGHT

The Knoxville Zoological Park currently holds two male spider tortoises *(Pyxis arachnoides)* and one male kapadola tortoise *(Acinixys planicauda).* These specimens are long-term captives (10+ years) that have not been in a reproductive situation for a number of years.

For the purpose of establishing a reproductive program for these species, anyone with female specimens or information as to the whereabouts of captive females of either species is urged to contact Bern W. Tryon, Department of Herpetology, Knoxville Zoological Park, P.O. Box 6040, Knoxville, Tennessee 37914, U.S.A. ●

MADRAS SNAKE PARK NEWSLETTER

Hamadryad, the Newsletter of the Madras Snake Park, is issued three times a year and welcomes contributions from herpetologists working in India and elsewhere in south Asia. The newsletter is edited by Zahida Whitaker and features articles on the activities and events at the Madras Snake Park, the Madras Crocodile Bank, and the Irula Tribal Snake Venom Cooperative. In addition, Romulus Whitaker and the MSP and MCB staff regularly report the results of fieldwork and surveys on herpetofauna throughout the Indian subcontinent and south Asia. Recent issues have featured sea turtles, freshwater turtles, crocodilians, and snakes. A sampling of the contents of *Hamadryad,* Volume 9, No. 3 (September 1984) included articles and notes on: the viper *Hypnale hypnale,* sea snakes, snakebite, oral antivenom, the Irula Snakecatchers Cooperative Society, king cobras hatched at the MSP, a freshwater turtle status report, olive ridley turtle rookeries in Orissa, and notes on *Hardella thurga* and *Trionyx nigracans.* An annual (3 issues) subscription is US $5 (sent airmail). Remittance in US dollars for subscriptions and requests for back issues may be sent to:

DEDICATION OF PLYMOUTH REDBELLY TURTLE REFUGE

On 22 October 1984 ceremonies were held in Plymouth, Massachusetts marking the establishment of the Massasoit National Wildlife Refuge to protect critical habitat for the Plymouth redbelly turtle *(Pseudemys rubriventris bangsi).* The refuge protects a 184-acre parcel of the turtles' limited habitat, and is the first federal refuge established for a freshwater turtle. The Plymouth redbelly turtle was designated a Federal Endangered Species in 1980, and the U.S. Fish and Wildlife Service has designated 3,269 acres in Plymouth as "critical habitat." The population is currently estimated at less than 300 individuals, restricted to approximately 15 Coastal Plain ponds.

The land that comprises the new refuge was initially purchased by The Nature Conservancy, a private conservation organization. In 1983 the U.S. Fish and Wildlife Service bought the parcel from the Conservancy and designated it a National Wildlife Refuge. The Fish and Wildlife Service has now entered into a cooperative agreement with the Massachusetts Division of Fisheries and Wildlife giving responsibility for managing and protecting the turtle population and habitat on the refuge to the Division's Nongame and Endangered Species Program. This is the first National Wildlife Refuge to be managed jointly by the U.S. Fish and Wildlife Service and a state wildlife management agency.

The Plymouth redbelly turtle is found nowhere in the world but Massachusetts, although a closely-related subspecies occurs in scattered colonies from southern New Jersey to North Carolina. The turtle was probably never abundant, although its current low population is attributed in part to loss of habitat to residential development. High rates of mammalian predation on nests are believed responsible for poor recruitment into the adult population. Research and management efforts for the Plymouth redbelly turtle are financed in part by the Massachusetts Non-

game Wildlife Fund created in 1983 to support nongame and endangered species conservation.

Further information about this refuge may be obtained from:

SOCIETIES

BRITISH HERPETOLOGICAL SOCIETY MEETINGS 1985

The meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1 and start at 7:00 pm unless indicated otherwise. For further details, please write to BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, England. As always, *SSAR members* and other North American herpetologists passing through or visiting London *are most welcome.*

February 28th The Earl of Cranbrook (President, BHS): The herpetofauna of Vanuatu (Pacific Ocean).

March 19th Annual General Meeting followed by a report by Professor Kraig Adler (Cornell University, U.S.A., and Pembroke College, Cambridge), Secretary-General: Progress in planning the first World Congress of Herpetology, and Dr. M.R.K. Lambert (Chairman, BHS): A few herpetofauna in the Commonwealth (Australia, Seychelles, Malawi, Zimbabwe).

April 25th Mr. Brian Banks (Biological Sciences, University of Sussex): Breeding ecology of the natterjack in Britain in relation to conservation. *Cancelled in 1984.*

May 15th Professor Kraig Adler (Section of Neurobiology and Behavior, Cornell University, New York and Department of Zoology, University of Cambridge): Sensory basis of amphibian orientation and navigation. Illustrated by North American species.

June 19th *Amphibians and reptiles worldwide. A discussion on care and breeding organized by the Captive Breeding Committee.

September 26th Meeting topic to be arranged by the Captive Breeding Committee.

October 23rd Dr. Alan Charig (Chief Curator of Fossil Amphibians, Reptiles and Birds, Department of Palaeontology, British Museum (Natural History), London): Dinosaurs: myths and misconceptions. *Carried over from 1984.*

November 19th Dr. Andrew Laurie (Department of Zoology, University of Cambridge): Marine iguanas on the Galapagos Islands (Pacific Ocean) and El Niño. *Date to be confirmed.*

*Members are encouraged to bring live animals, preserved specimens and 35 mm slides for display and to illustrate discussions. ●

TEXAS HERPETOLOGICAL SOCIETY

The plan to organize a Texas Herpetological Society was conceived in November, 1938, during a meeting of the Texas Academy of Science. Four members, prompted by the inconvenience of sitting through a long session of formal papers, thought of a new type gathering. The first field meet was held at San Marcos, Texas, April 15-16, 1939. The atmosphere of informality present at the first field meet has become a tradition with the Society.

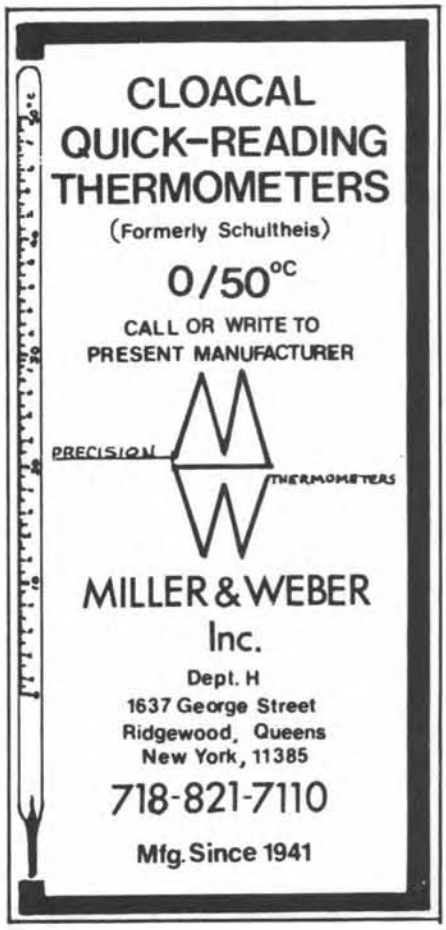
Field meets have been held each year since 1939, except for the war years of 1943 to 1945. In 1941 a constitution was adopted embodying the plan of the group. Attendance at meetings has varied from 28 to over 100 interested persons. Members include amateur and professional herpetologists, young and old. In 1973 the Society instituted an annual Fall Meeting and banquet.

The Society is proud that many of its present and former members have contributed to the advancement of herpetology in Texas and elsewhere. These contributions include the introduction of college courses on the subject, herpetological research in universities, museums and zoos, and scholarly publications dealing with amphibians and reptiles and the science of herpetology.

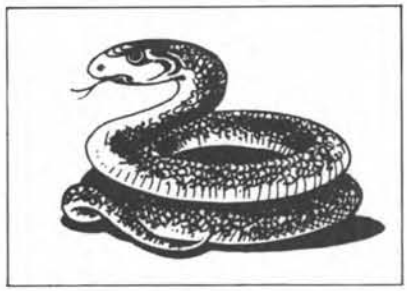
The activities of the Texas Herpetological Society include:

(1) An annual Spring Field Meet on a weekend, usually mid-April or early May; includes collecting, identifying, exhibiting and inventorying herpetological species, camping out, campfire meals, a business meeting and fellowship among herpetologists.

(2) An annual Fall Meeting usually in November, featuring distinguished speakers, seminars, workshops, panel discussions, exhibits, tours of zoos, museums and research facilities, a business meeting and a banquet.



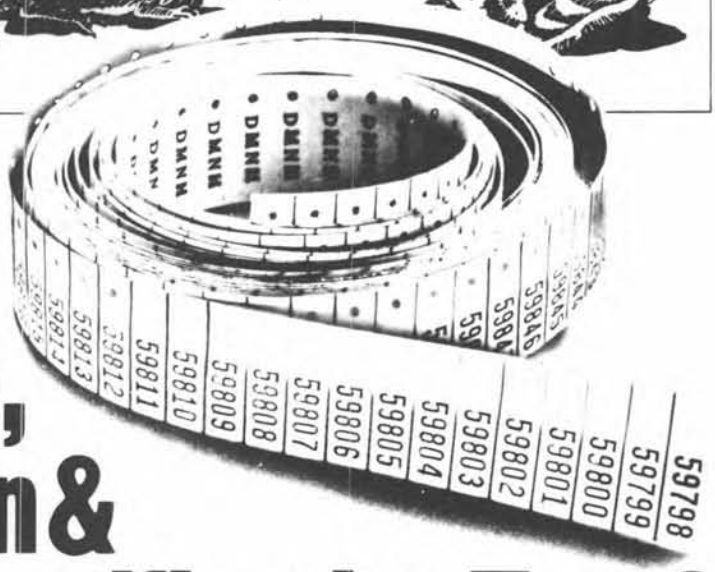
(3) An informal Newsletter distributed twice a year to inform membership of research activities, collection records, general information on members, and scheduled meetings of the Society.



The purpose of the Society is to promote the discovery and dissemination of knowledge of amphibians and reptiles, to encourage specifically the study of amphibians and reptiles in Texas, to encourage conservation of wildlife in general and of amphibians and reptiles in Texas in particular, and to stimulate fellowship among herpetologists of Texas and the Southwest.

There are three membership categories. Active membership is open to those who adhere to the purposes of the Society. Subscriber membership is available to any person or group who wishes to receive the Society's Newsletter. Honorary membership is conferred on any person who has made significant contributions to Texas herpetology. An Honorary member is nominated by a member, screened by the executive board, and elected by 2/3 vote of members present at a business meeting.

Dues are $6.00 for regular Active Member, $3.00 for student Active Member, and $3.00 for Subscriber Member. For additional information about the Texas Herpetological Society contact:



Terry Hibbitts, Secretary-Treasurer
Texas Herpetological Society
309 South 4th Street
Wylie, Texas 75098, U.S.A. ●

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Stop your searching. Here are those identification tags you've been looking for. Save time, money and patience simply by ordering them right now from the NATIONAL TAG COMPANY. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on both sides.

*Note: Stock tags are consecutively numbered, but the starting number will vary for each shipment. There's no printing on back side. Custom tags can get any numbering sequence desired, with or without prefix letters, plus printing on the back side (illustration above).

NATIONAL TAG COMPANY, 815 S. Brown School Rd., Vandalia, OH 45377

HERPETOLOGICAL ACTIVITIES IN EUROPE 1983 — A REPORT

Apart from ongoing herpetological research work in Universities, Museums and other organizations, which will be published in due course in the Old and New Worlds' recognized scientific journals, several meetings were organized by the Societies during 1983. The most significant were probably the 2nd Ordinary General Meeting of multinational Societas Europaea Herpetologica (SEH) in León, Spain; the 1983 meeting of the Deutsche Gesellschaft für Herpetologie und Terrarienkunde e.V. (DGHT) in Zürich, Switzerland, also in September; the annual meeting of the Société herpétologique de France (SHF) in Montpellier, France, earlier in the year, in May, and the two-day international symposium on reptile biology (reported on separately: *Herp. Review 15*(1):6, also held in May by the Zoological Society of London and organized jointly with the Anatomical Society of Great Britain and Ireland and the British Herpetological Society (BHS). Further details of these and other activities will be given under the countries in which they were held, based on reports in the form of bulletins, newsletters and journals that have been received. The compiler at this preliminary stage has attempted completeness and accuracy, but regrets any omissions or errors, at the same time taking this opportunity to request that herpetological societies and other organizations in Europe forward him details for consideration and inclusion in a 1984 and future reports. Information is particularly lacking for northern Europe (perhaps where the least number of species occurs!), especially Scandinavia, the Netherlands and the Eastern European Block. Countries for which information is to hand are considered alphabetically, but commencing with societies of multinational involvement.

Europe

The 2nd SEH O.G.M. was held in León, Spain, 12-16th September. There were 82 registrants from Spain (35), the Netherlands (12), F.R. of Germany (11), France (8), Sweden (4), Poland (2), UK (2), Austria (1), Czechoslovakia (1), Italy (1), Norway (1), Portugal (1), USA (2) and Australia (1). The meeting was organized by Prof. Alfredo Salvador (SEH Vice-Secretary) and held in the Faculty of Biology, University of León. A total of 38 papers on a wide range of subjects was read at the meeting, which included a symposium on Biogeography of the Western Mediterranean and as a special topic, Biochemical Methods in Systematics. As the Society's official language, most papers were read in English, but some were delivered in French, Spanish and German with abstracts in English circulated with the programme beforehand. A full report will appear in due course in SEH's journal, *Amphibia-Reptilia*, the new publisher now being E. J. Brill —Leiden, the Netherlands and another in the *BHS Bulletin* with an informal account of the two excellent field excursions into the Cordillera-Cantabrica range and Sierra Cabrera of NW Spain.

The SEH Conservation Committee, chaired by Keith Corbett (London), is also initiating ecological investigations into the status of the rarest species of European herpetofauna as the result of successfully presenting to the Council of Europe in Strasbourg a three-phase strategy for the establishment of 'biogenetic reserves' and obtaining agreement that the herpetofauna (as indicator species) should be the first faunal grouping to benefit from them. With funds made available, the contract started in 1983.

The first phase is a written report and proposals based on knowledge already available on e.g. marine turtles, island endemics, species of restricted range etc. The second phase is a field assessment of the status of the most threatened species: *Vipera u. ursinii, V. u. rakosiensis, Proteus anguinus, Gallotia simonyi, Rana latastei* and *Pelobates fuscus insubricus*. The third phase (and most expensive) involves placing two researchers from the University of Nijmegen (the Netherlands), each for a season, into chosen areas of Europe where a number of threatened and typical endemics exist. Sardinia and southern Greece have been selected as prime target areas. The SEH, through the aegis of the Muséum national d'Histoire naturelle, Paris, are also proceeding with the comparative mapping of the herpetofauna of Europe for regional and national conservation measures.

Implementation of the 1981 Berne Convention on the Conservation of European Wildlife and Natural Habitats has been good in Switzerland; in the Netherlands, all species have been protected and special projects for *Alytes obstetricans, Bombina variegata* and *Podarcis muralis*, and one for 1000 ponds (in line with the 1983 European Year of the Water's Edge) have been initiated. In the UK, there was the 'save the toad' campaign, organized by the Conservation Officer of the BHS; in addition, the Nature Conservancy Council instigated an enquiry into the status of the great crested newt *(Triturus cristatus)*, now listed as endangered in Britain. Italy and other countries no longer gave licenses to export *Lacerta viridis* and *Triturus carnifex*, which were formally involved in the pet trade. The Ramsar Convention (1975 Convention on Wetlands of International Importance especially as Waterfowl Habitat) has been extended to include the herpetofauna and other groups. But on a more serious note; of a total of 400 projects submitted to the EEC (European Community) for funding, 80 have been approved, but none included any herpetological work when some was of international priority.

Eastern Europe

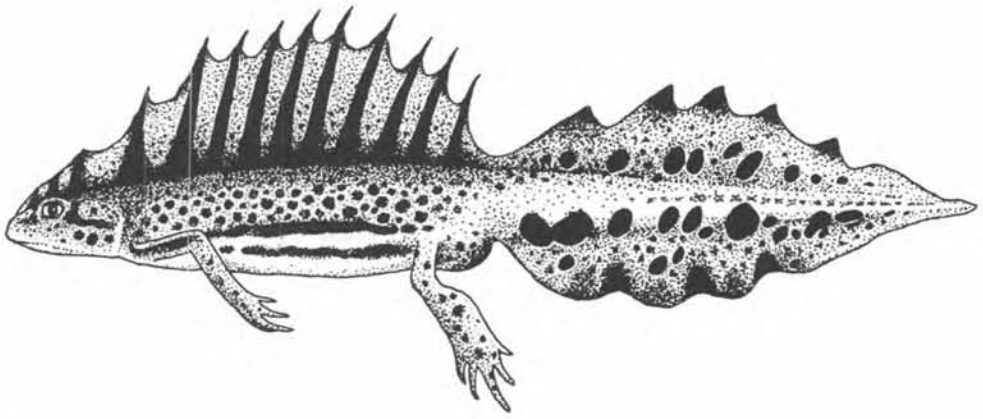
The 1983 Herpetological Conference of the Socialist Countries was held in the D.R. of Germany (the first was held in 1981 in Budapest, Hungary). Through correspondence between Drs. Josef Eiselt, President of SEH, and Ilya Darevsky of the Soviet Union, and as the result of a decision in 1983 by members of SEH at their meeting in León, it has been decided that a meeting in 1985 will be held in Prague, Czechoslovakia, 19-23rd August, at Charles University, which is presently being organized by Dr. Zbynek Roček of the Department of Palaeontology in the Faculty of Natural Sciences.

Countries

Belgium: The recent build-up in an interest in conservation of amphibians and reptiles, and other wildlife, in Belgium (parts of the country suffer particularly seriously from industrial pollution) was reflected by the publication especially of the book by Prof. G.-H. Parent: *Protégeons nos batraciens et reptiles* as one of a series with birds, mammals and fish of *Animaux menacées en Wallonie*. This is a useful, nicely produced little book, the main aim of which is to outline the status of the herpetofauna in the southern (French-speaking) part of Belgium. It is a pity that the coverage is not for the whole of Belgium, although another, more general publication, including a section on the herpetofauna, has been separately produced for Flanders (northern, Flemish-speaking Belgium).

A proposal has also been made in Belgium to set up a group to prepare an inventory and to study and protect *R*eptiles and *A*mphibians in *N*ature (RANA). The name RANA has been chosen because this abbreviation is the same in all European languages and because the 'real frog' (*Rana*, F. Ranidae) is usually popular and quite well known to the public at large. It is intended to improve the image of amphibians and reptiles and to make them better known and more popular, and at the same time to save the most endangered species. The RANA frog symbol is to figure on a sticker, a poster and on a guide for all of the species and will be in several languages. A poster will be produced initially for the amphibia of Benelux (Belgium-Netherlands-Luxembourg); later a guide on the amphibia will also be published , in English, by a publisher in the UK (David & Charles, Newton Abbot) written by Donato Ballasina (Tervuren). RANA groups have also been set up in France and Italy.

France: The *Bulletin de la Société herpétologique de France* reflected an active year in 1983 for herpetology in France. Number 26 (the second issue) reported on the 1982 annual meeting of the SHF at Clermont-Ferrand in the Auvergne in which ten papers were presented on the special theme: the viviparous lizard and viviparity, in addition to a further seven on a wider range of subjects including one (as one might expect) on the reptiles and amphibians of the Auvergne, and totalled 58 pages. A trimestrial publication, numbers 25, 27 and 28 included eight (71 pp.), five (70 pp.) and three papers (70 pp.), respectively. The 1983 annual meeting was held in Montpellier, 30th June to 2nd July, and was organized by the SHF Secretary, Cl. P. Guillaume, with assistance from colleagues at the Laboratoire de Biogéographie des Vertebrés, Ecole Pratiques des Hautes Etudes of the University of Montpellier. Papers were presented on the general theme: the systematics and biogeography of the amphibians and reptiles of France, and the meeting was attended by a record 104 participants and deemed a great success. Dr. Edward Elkan (London), an authority on the pathology of the lower vertebrates (BHS Honorary Member 1982), was elected an Honorary Member of the SHF. Sadly he died (4th July 1983) only two days after this honour was bestowed upon him and an Obituary by G. Matz was



published in *Bulletin SHF* No. 28. Dr. Elkan was to have been the guest of honour at the First International Colloquium of the Pathology of Reptiles and Amphibians held at Angers, France, in September 1982, but regrettably ill health prevented his attendance. At the Montpellier meeting, a new 'Commission' of the SHF was approved under the Chair of Miss L. Bodson (University of Liège, Belgium) on ethnoherpetology and the history of herpetology. It was agreed that the 1984 annual meeting would be held at the University of Rennes, 28th June to 1st July, with the principal theme: reproduction; the sexual cycle of amphibians and reptiles.

Two further meetings were held later in the year in France and involved an herpetological interest. An International Conference on the Terrestrial and Freshwater Vertebrates of the Mediterranean Islands (origin, status, human influence and conservation) was held at Evisa on Corsica, 10-16th October, and was organized by Profs. C. Blanc and J.-N. Lheritier of the Zoogeography Laboratory, Paul Valéry University, Montpellier. The First International Symposium on Fossil Turtles was held by the Institute of Palaeontology, Paris, 12-14th October, and was attended by established specialists in the field.

The Société batrachologique de France (founded 1981) has continued to publish *Alytes*, edited by Dr. Alain Dubois of the Muséum national d'Histoire naturelle, Paris. With 1983, one issue (no. 3, September) of its second volume addressed the important question of frogs' legs as a culinary delicacy in France and its impact on the natural populations from whence the animals are collected. Dr. Dubois discussed the whole issue ('A propos de cuisses de grenouilles') and ended with some general proposals on the part of the Society. It would be useful if this article could be translated into English and published in a journal of wider circulation, not necessarily just of herpetological interest.

Finally, the Secretariat of Fauna and Flora at the Muséum national d'Histoire naturelle, Paris, established a code of practice relating to the preparation of an inventory of animals and plants and their habitats, and on the collection and collation of data for the preparation of distribution atlases. This is of importance to herpetology in Europe, for it was agreed at the 1983 SEH meeting in León that the preparation of a European amphibian and reptile atlas would be undertaken in France in collaboration with members of the SEH Conservation Committee. Distribution data collection sheets have already been published in France by the Secretariat at the Museum in Paris.

Germany, Democratic Republic (DDR): The Zentraler Fachausschuss (ZFA) Terraristik of the Kulturbund der Deutsche Democratische Republik publish *Elaphe* quarterly. This is the 'Arbeitsmateriel des ZFA Tarraristik' in which the Zentralen Arbeitsgruppen (ZAG) publishes articles. ZAG (working groups) exist for lizards, snakes, tortoises/turtles, amphibia and small mammals. The journal consists of short articles on different species, stressing their rearing and breeding in vivaria, and book reviews. The first issue of *Elaphe* included a 1983 programme. Two business meetings were each held at Berlin and Halle, the specialist group business seminar at Dresden in March and the fifth joint meeting at Schwein, 28-30th October. The Lizard and Snake working groups also reported on their quite extensive activities in breeding during 1983 and a display of exotic amphibians, reptiles and small mammals, and insects, was held in the Botanic Garden of Halle (Saale), 18th June to 3rd July.

Germany, Federal Republic (BRD): The big German society, the DGHT, held its 1983 meeting in Zürich, Switzerland, 7-11th September. Unfortunately, this was just before the SEH meeting in León, Spain, 12-16th September. Twenty papers were read on a wide range of herpetological subjects including one on a revision of the *Tarentola* geckos by U. Joger (Marburg), who also managed to attend the SEH meeting and read his paper there too! A discussion on the distribution and mapping of central Europe was lead by Richard Podloucky (Hannover).

The Rundbrief (DGHT newsletter) numbers 76, 77, 78 and 79 (a total of 125 pages) were circulated during 1983 and gave information on the financial state of the Society, current policy, items of conservation interest (a deep concern plainly being expressed in this subject), listing of new members and their addresses, address changes, members resigning, indication of meetings, news of state and country groups and members' offers-requests-exchanges relating to a general herpetological interest and species in vivaria. The more formal publication of the DGHT, *Salamandra,* includes specialist papers on a wide range of subjects from rearing and breeding species in captivity to ecology and distribution. Volume 18(1/2, pages 1-120) appeared during 1982, but volume 18(3/4, pages 121-368) December 1982 did not appear until February 1984 and, as an international journal for herpetology, included papers in English and summaries in French. It was, however, announced in Rundbrief no. 76 (February 1983) that as an organ of the DGHT, the publication of papers in English and French summaries would be discontinued. Volume 19 (1/2 and 3/4) was published in 1983 and included an Obituary by Dr. Konrad Klemmer (Past President of DGHT) on Dr. Hans-Günter Petzold of Leipzig Zoo, who died on 19 November 1982.

The publication *Herpetofauna* is another journal produced in F.R. of Germany primarily for vivarium keepers. Six issues are produced annually and during 1983, volume 5, numbers 22-27 were published, each number totalling about 30 pages.

Israel: During 1983, the Israel Herpetological Information Center (IHIC), based in Jerusalem, published a journal *Hardun*. The first issue (no. 1) appeared in February and contained articles in English (pages 68-57) and others in Hebrew (pages 1-56).

Italy: A red list of the herpetofauna of Italy was published in 1983 by Dr. Silvio Bruno (Pescasseroli) and as a result of several years work under the auspices of the Centro di Studio per la Faunistica ed Ecologia Tropicali (Consiglio Nazionale delle Ricerche, Florence), Prof. B. Lanza submitted his check list of the amphibians and reptiles of Somalia for publication.

Netherlands: The oldest European society (founded 1942), Lacerta (Nederlandse Vereniging voor Herpetologie en Terrarienkunde) publishes a journal of that name monthly, together with an information sheet, which, with reports from the eleven local branches in Holland, outlines the day-to-day activities of the Society and events of herpetological interest. *Lacerta* includes semi-popular articles in the Dutch language mainly on keeping species in vivaria and on herpetological observations made on excursions to various parts of the World. Several articles on different species of terrapin were published during 1983 and the last three numbers of the year (42nd volume, numbers 1-3, pages 1-60) each included short accounts of the herpetofauna of Costa Rica.

Spain: The newly formed Societat Catalana d'Ictiologia i Herpetologia publishes a small Bulletin quarterly, which contains short articles in Catalan on the lower vertebrates mainly of Catalonia (NE Spain). Under the Presidency of Dr. J. Maluquer i Nicolai (Barcelona), the members totalled 34 by June 1983. An effort is being made to catalogue the

lower vertebrate fauna of Catalonia and printed cards have been prepared to complete details on the species, habitat and localities.

Co-edited by Prof. H. Hemmer (Mainz, F.R. of Germany) and J. A. Alcover (Barcelona), a multiauthored monograph on the living fossil, the Mallorcan midwife toad (*Alytes (Baleaphryne) muletensis*), was in preparation during 1983 and is to be published by Editorial Moll, Palma de Mallorca as Monografias Cientifiques no. 3.

The bimestrial *Vida Silvestre*, a periodical published by ICONA, Madrid, and beautifully illustrated with high quality coloured photographs, frequently includes articles on the herpetofuana of Spain. Number 45 (March 1983) included an article on *Triturus marmoratus* (Triton Jaspeada) by Javier Andrada with magnificient photographs in full colour.

But probably of greatest importance herpetologically in Spain during 1983 was the 2nd O.G.M. of SEH in León (NW Spain), 12-16th September (see earlier). Thirty-five of the 82 registrants were from Spain and the meeting plainly gave the opportunity for Spanish herpetologists to present papers on their work and to meet other European researchers. Several papers on Spanish work had previously been published in SEH's *Amphibia-Reptilia*, including a note on the 'rediscovered' *Alytes (Baleaphryne) muletensis* on Mallorca, 8th September 1978, in volume 1 (3/4):343-345 (April 1981), and a paper on *Gallotia simonyi*, believed to be extinct until 1975, from the Canary Islands in volume 1 (2):369-380 (March 1982).

Sweden: The Sveriges Herpetologiska Riksförening, an association of six local herpetological societies in Sweden, publishes *Snoken* five times annually. In 1983, most of the articles were on snakes, as perhaps the name of the journal would imply, but others included one on an expedition to the Sahara Desert and another to Mount Ararat, E Turkey, and an account of giant tortoises in the Galapagos, Pacific Ocean. A symposium was held in Uppsala, 24-25th September.

Switzerland: The major herpetological event in Switzerland in 1983 was undoubtedly the meeting of the German DGHT in Zürich, 7-11th September (see earlier), under the patronage of the Zoological Museum and Zürich University. In consequence of this meeting immediately beforehand, no Swiss herpetologist attended the SEH meeting in León, Spain. Eight of the 20 papers presented were by Swiss workers. The meeting was organized by Henri L. Kratzer. The excursions included visits to the Zoological and Botanic Gardens.

Elapsoidea: fondation culturelle in Geneva also offered a programme of herpetological events during 1983, including an exhibition and talks ranging from the snake fauna of the Geneva valley to snakebite and reptile pathology.

United Kingdom: The unusual amount of herpetological activity in 1982 in the UK continued into 1983. The BHS held its 36th Annual General Meeting in London on 22nd March. Membership totalling 766 at the end of 1983 (c. 700 in 1982) included 98 from overseas (79 in 1982). Three new Honorary Members were announced: Prof. J. L. Cloudsley-Thompson (London), Prof. R. Conant (Albuquerque, New Mexico) and Dr. D. G. Broadley (Bulawayo, Zimbabwe); Mr. J. D. Romer (Hon. Member 1958) died in 1982. The business matters were followed by a talk by Lionel Kelleway (Swansea): Control of reproductive behaviour in the adder, *Vipera berus*, and included a 16-mm research film on sparring. Three further evening lectures were given on a range of subjects and members attended a meeting of the Linnean Society of London on the chromosomes of European crested newts by Prof. H. C. MacGregor and co-researchers at the University of Leicester in April. Besides the two discussions on New and Old World species and the July visit to the London Zoo during a Zoo Members' Open Evening, the Captive Breeding Committee jointly held a successful Saturday meeting with the British Veterinary Zoological Society in October for which Proceedings will be published. A joint meeting was also held with ASRA (Association for the Study of Reptilia and Amphibia, Oxfordshire) at the Cotswold Wild Life Park.

An undoubted highlight of the year, however, was the most successful two-day symposium on reptile biology held at the Zoological Society of London in honour of Prof. Angus Bellairs (BHS Hon. Member 1982) on the occasion of his retirement and organized jointly with the Zoological Society and Anatomical Society of Great Britain and Ireland by Prof. Mark Ferguson (Belfast, Northern Ireland; now of the University of Manchester). A Festschrift volume as no. 52 of the *Symposia of the Zoological Society of London* (published by Academic Press) appeared in 1984 (September). An enjoyable social occasion shortly before Christmas (16th December) was provided by the first Malcolm Smith Dinner, hosted by the President of the Society, the Earl of Cranbrook, and held in the Peers' Dining Room, House of Lords, Westminster (reported on separately: *Herp. Review* 15(1):12). The President gave a speech (published later in the *BHS Bulletin* no. 9:2-5, June 1984), which was replied to by Dr. R. F. Inger, then President of the Herpetologists' League, USA. Miss A.G.C. Grandison of the Amphibian Section of the British Museum (Natural History), London, was also an invited guest.

BHS Council members represented the Society's interests at meetings of the UK Committee for IUCN, the Wildlife Link and the 2nd O.G.M. of the SEH at León, Spain. An account of the BHS's work was read in August on behalf of M.R.K. Lambert by Kraig Adler at the SSAR's 7th Annual Conference of the Regional Herpetological Societies at Salt Lake City, Utah.

1983 also saw as a special publication of the BHS (organized by the Captive Breeding Committee) Nicholas Mrosovsky's book *Conserving sea turtles*, which was widely reviewed; that of Peter Pritchard in the American Society of Ichthyologists and Herpetologists' journal *Copeia* 1983 (4):1108-1111 being of particular note. The BHS past President until 1981, Dr. J.F.D. (Deryk) Frazer, published his rewrite of the BHS founding President, Dr. Malcolm Smith's book (1951, revised 1954) on the British herpetofauna under the title *Reptiles and amphibians in Britain* (Collins' New Naturalist Series no. 69). As a breakthrough in the field of herpetofaunal conservation in Britain, the Nature Conservancy Council (NCC) finally published their report *The ecology and conservation of amphibian and reptile species endangered in Britain* (93 pp) as promised six years earlier at a meeting with members of the BHS Conservation Committee in January 1977. The report covers three (*Bufo calamita, Lacerta agilis* and *Coronella austriaca*) of the four rare and endangered species in Britain; *Triturus cristatus* was protected later with the 1981 Wildlife and Countryside Act, the NCC now having initiated work on this species too. The NCC have agreed (16th March 1983) to use this report as the basis for their policies and programmes for the species covered and commended land managers and decision-makers to use it likewise. However, when considering proposals for translocations, they would normally intend to exercise their powers and duties in ways that would seek to minimize the mixing of genetic material from the various populations of each species. As a contribution to the discussion on the relocation of the herpetofauna in Britain in light of this, the BHS Conservation Committee have issued a statement (*British Journal of Herpetology* 6 (8):314-316), which has been submitted to NCC for comment. Britain and Ireland are biogeographically offshore NW European islands, and the hard experience gained in conserving the British species is being put to use on the continental mainland. Keith Corbett, as a founding member of the BHS Conservation Committee (1969), has become chairman of the SEH Conservation Committee (founded 1981), and during 1983 (after meetings in 1982 in Hannover, Strasbourg and Genoa) visited Hardwijk (Netherlands), Nijmegen and Paris, the last, in October, to discuss the mapping of the European herpetofauna and their habitats in relation to future conservation.

The *British Journal of Herpetology* published 17 papers and three notes in volume 6 (8 and 9), pages 281-350, on a wide range of subjects during 1983, including work on the gharial (*Gavialis gangeticus*) in India by H. R. Bustard, a description of a new species of *Psammophis* from northern Ghana by S. Spawls and on the endangered British species and their habitats by several authors. The *BHS Bulletin*, pages totalling 140 in 1983, included a list of the herpetological societies of Europe and the Commonwealth and an outline of research work in some of the British Universities (no. 7, June), and an article on the future role of the BHS in the Commonwealth and two on herpetology in New Zealand and India (no. 8, December).

ASRA, Oxfordshire, has decided to publish the papers on captive husbandry and breeding, and general herpetology, read at the International Herpetological Congress held at Oxford, October 1981, in *ASRA Journal* 2 (1-4). Volume 2, numbers 1 and 2, totalling 153 pages, were published in 1983 and comprised fourteen papers including T. Joanen and L. McNease on captive propagation of alligators in Louisiana, Ch.P. Blanc on the Iguanidae of Madagascar: VIII. Stages and factors involved in their evolution, R. C. Bruce on larval salamander communities in the

southern Appalachians and W. R. Branch on the captive breeding of pythons from work in South Africa.

At the end of 1983, the British Chelonia Group, Bristol, published the Proceedings B of the 2nd European Chelonian Symposium, Oxford 1981, in their journal *Testudo*. Volume 2 (2), pages 1-32, included the papers of more general interest and titles of those presented which were or have been published elsewhere, other than in Proceedings A, which were published by SEH's *Amphibia-Reptilia* (December 1984).

As a final word, the compiler apologizes for the UK bias in this report and reiterates his request for information from herpetological societies and other organizations elsewhere in Europe to redress the imbalance for any future report. Thanks are due to Dr. Marinus S. Hoogmoed (Rijksmuseum van Natuurlijke Historie, Leiden, the Netherlands), SEH General Secretary, for reading a draft of this manuscript and briefly commenting helpfully on it.

Selective Use of Pitfall Traps by Southern Leopard Frogs

Pitfall traps have been widely used to sample reptile and amphibian populations (e.g. Storm and Pimentel 1954; Pearson 1955; Nelson and Gibbons 1972; Gibbons and Bennett 1974; Bennett et al. 1980; Semlitsch et al. 1981; Semlitsch 1983), but few researchers have quantified, or even acknowledged, biases of the trapping technique. Factors such as body size, home range size and trap avoidance behavior influence the rate and patterns of capture of herpetofauna (Gibbons and Semlitsch 1982). For example, Gibbons and Semlitsch (1982) noted that eastern box turtles *(Terrapene carolina)* actively avoided pitfalls; only three specimens were captured during a year of sampling despite the abundance of this turtle on their study area. In this note I describe another behavior-related bias: the selective use of pitfall traps by southern leopard frogs *(Rana utricularia)*.

From 2 May to 5 December 1983 I conducted a study of the diversity and activity patterns of the herpetofauna of a hardwood forest in Scotts Hill, Pender County, North Carolina. Herpetofauna were sampled using pitfall traps consisting of 15.5 cm diameter X 16.5 cm deep aluminum cans placed in holes with their rims flush with the soil surface. One-hundred pitfalls were placed at 10 m intervals in a 10 X 10 grid. Traps were checked weekly and all specimens were individually marked by toe-clipping, measured, and released at the site of capture. The pitfalls did not have drain holes in the bottom and nearly always contained several centimeters of water from precipitation. Traps containing > 5 cm of water were bailed out on each visit.

On three occasions during October and November 1983 I observed southern leopard frogs jumping into pitfalls upon my approach. This behavior suggests that frogs may have been using pitfalls as a refuge from predators while foraging terrestrially. Brimley (1943) stated that southern leopard frogs readily plunge into water when alarmed. The fact that frogs were sitting near the pitfalls before I approached further suggests that they may have been using the traps for other purposes, such as maintenance of water balance while traveling over land.

On 12 November a total of 19 southern leopard frogs was captured, the largest number trapped at one time during the study. Four pitfalls contained two frogs each and one trap held three frogs. Only one other instance of multiple captures was recorded during this study. While removing frogs from the traps, I noted that water in the traps felt noticeably warmer than the air. Temperature data obtained from the National Weather Service office in Wilmington, North Carolina, 15 km southwest of the study site, indicated that temperatures on the 12th were below normal. The early morning low temperature was 2° C and the average daily temperature was 8° C, 6 degrees cooler than normal. The high reached only 13° C. The average temperature for the previous day was 15° C, with a high of 20° C. Water temperature does not change as rapidly as air temperature, owing to the greater specific heat and high latent heat of evaporation of water (Wetzel 1975). Presumably, water in the traps warmed on 11 November remained relatively warm while air temperature on the 12th dropped to 2° C. Because traps were checked weekly, the number of frogs entering the pitfalls on the night of 11-12 November was unknown. However, the large number of frogs found in pitfalls on 12 November suggests that when the air temperature dropped, frogs actively sought out the warm water in the pitfalls for thermoregulatory purposes. In the laboratory, the closely related northern leopard frog *(R. pipiens)* generally seeks shelter under objects in the bottom of an aquarium when temperatures drop below 8° C (Porter 1972). In the wild, northern leopard frogs are usually found in water on nights when the air is cooler than the water (Brattstrom 1963).

Southern leopard frogs breed in ponds, river swamps, ditches and other wetlands (Wright and Wright 1949), but scatter throughout uplands after the spring and summer breeding season (Brandt 1936). While traveling on land these frogs are subject to desiccation, predation and fluctuating air temperatures. Pitfall traps containing water may provide a refuge from dry conditions, terrestrial predators and cold nighttime temperatures.

Preferential use of pitfalls by southern leopard frogs during this study resulted in a trapping bias that increased the number of frogs captured. This potential source of bias should be recognized by other researchers using pitfalls that may hold water. Individual marking of animals is essential to detect such biases, which may be decreased by placing holes in the bottom of pitfall traps to drain the water.

ACKNOWLEDGMENTS

This study would not have been possible without the assistance of P. B. Colwell and W. D. Webster.

USES OF SOME REPTILES BY THE YORUBA PEOPLE OF NIGERIA

The purpose of this essay is to inform the herpetological community of reptile use by the Yoruba, a West African tribe, and to relate some anecdotes concerning folklore of these animals. This information has never been reported in the literature and was obtained through a series of opportunistic interviews with a Yoruba woman named Rachel Falade from the village of Ifon, Ondo State, Nigeria in the latter part of 1981. Some readers may feel that the account lacks validity since only one interviewee is involved. But much of the information concerns the practice of traditional medicine, witchcraft, and religious practice which Africans are not often disposed to discuss with outsiders.

The Yoruba, located principally in the Southwest quarter of Nigeria and extending into Benin and Togo, are one of the three major tribal factions of Nigeria along with the Northern Hausas, and the Southeastern Ibos. The culture had organized kingdoms in the cities of Oyo and Benin by the 15th century according to Portuguese accounts (Lloyd 1965). They are world renowned for their brass and terra-cotta art treasures. Though most now profess Christianity and to a lesser extent Islam, traditional beliefs are much a part of everyday life for the Yoruba.

Several authors have discussed witchcraft and religion among the Yoruba (Bascom 1944; Morton-Williams 1954; Prince 1961). Others have considered various medical practices of Yoruba native doctors (Prince 1962; Soyanwo 1962; Maclean 1965; Odebiyi 1976; Oyebola 1980). But no one, to my knowledge, has approached these topics from the perspective of the uses of a particular group of animals in such practices.

The list of ingredients for the concoctions as reported herein are assumed to apply to this village only, since the recipes are likely to vary from village to village and certainly from tribe to tribe over all of West Africa. It is also not the purpose of the authors to scrutinize the physiologic efficacy or the psychological advantages of the medicines although in some cases comments of this nature are included.

Information concerning the use of skins is presented from personal observations by the authors and is not intended to single out usage by any particular tribe.

Python regius - Royal or Ball Python

During my inquiries I (JAB) referred to this python as the smaller of the two Nigerian species and was informed that the Yoruba call it "oka." They attribute its shyness (balling behavior) to the idea that the snake is attempting to hide its tail because this is the source of its power. According to myth, if one were to step on the head of a royal python no harm would come, but to step on the tail would mean certain death. It is unclear whether myths concerning this snake's tail originate from the presence of vestigial limbs or the harmless horny tip—or neither. Vague myths concerning tails of other snakes are prevalent in Nigeria, as evidenced by the fact that when handling any species of snake I was continually warned by Africans about controlling the tail. Also, most if not all snakes are used as food by the Yoruba, and it is common practice to bury the snake's head with the tail in the mouth before cooking the body. I have been unable to determine the origin of this practice.

The head of a royal python can be used for evil purposes by the Yoruba through their native diviners ("juju men"). If one does not want an enemy to progress in life, he goes to the diviner—called Babalawo—with the complaint. The Babalawo mixes the dried head of the python with other unidentified objects into a solution. While mixing, various incantations are said and the victim's name is spoken. The victim is then tricked into drinking some of the solution, and from that point on he will be impeded from progressing further in life.

The royal python can also be used to bring good fortune, such as finding a wife or getting a better job. All one needs to do in this regard is to bring a part of the snake — usually the tail — to the Babalawo. This is dried and then burned to ash. Cuts are then made in the skin of the solicitor, and the ashes rubbed into the cuts. The ashes enter the blood and confer the individual's wishes.

Python sebae - African Rock Python

The rock python, as well as most other snakes in West Africa, can be used as food. They are called "ere" in Yoruba. The fat of the abdominal cavity is also used as a rubbing ointment said to soothe muscle aches and sprains, arthritis, and rheumatism.

Probably the most common use of the rock python in West Africa is the collection and sale of its skin. A skin from a 5-6 meter snake can fetch one hundred naira (about $150) or more. Python skins are sold openly by tradesmen at beaches or hotels frequented by expatriates, in all major cities.

Chamaeleo sp. - Chamaeleon

There are seven species of chamaeleon (Yoruba = "oga") in Nigeria and the Yoruba may normally encounter three: *C. gracilis, C. basiliscus,* and *C. senegalensis.* These three species are quite similar, differing most obviously in the size of their occipital lobes. When I asked if the Yoruba differentiate among the species, I was told that it was similar to the situation of black and white humans; we differ so very little that essentially we are the same.

A color change from brown to green which occurred in an adult *C. gracilis* as we spoke was attributed to a breeze from an open window entering the room through a green curtain. The Yoruba believe that the chamaeleon can see both the future and the past, since the eyes move independently. They also recognize that it can see in two fields of vision.

The origin of another Yoruba belief concerning chamaeleons is more difficult to ascertain. It is presumed that if one steps in the excreta of a chamaeleon he will develop elephantiasis. This idea is perplexing since the disease is usually caused by a filarial worm, *Wuchereria bancrofti,* the immature form of which is passed to humans only through the bite of several mosquito vectors.

The entire body of a chamaelon may be substituted for the royal python head by the Babalawo in the mixture which obstructs an enemy's goals. The chamaeleon is also used in a beneficial concoction said to cure convulsions in children.The only explanation of the cause of these convulsions was that they were associated with high body temperatures. Convulsions, of course, would be expected with high fever, and the fevers could be the result of a myriad of illnesses.

This medicine is prepared by mashing any part of the dried chamaeleon with the anal scent gland of a civet *(Viverra civetta)* and 5 to 10 fruits or seed pods of the spice *Xylopia aethiopica* (Yorba = "eru"). This is then mixed with sponge-like fibers, most likely from *Momordica angustisepala* (Yoruba = "okofe"). This mixture is added to the oil extract of the palm kernel, *Elaeis guineensis,* and is then rubbed on the body to stop convulsions. The physiologic efficacy of such treatment is suspect. It is interesting that this remedy is not used for adults since it is believed that adult convulsions are caused only by epilepsy, against which no native medicine is effective.

Varanus niloticus - Nile monitor lizard

This lizard is called "awonriwon" by the Yoruba. It is used as food and I have seen numerous dried specimens for sale at the open Dugbe market in Ibadan. Monitor skins are identifiable in shoes and handbags sold by craftsmen throughout Nigeria. The skin of the monitor is also used for the head of a drum which can only be used by a Babalawo for calling the god of the future, called "Osayin." The skin is attached to the drum, scale-side down, and is used because it is said to be very tough.

Kinixys sp. - Hinged tortoise

The several species of hinged tortoise are collectively called bush turtles or "igapa igbo" by the Yoruba. Their parts are used in a variety of remedies, and because they are important medicines, the head and intestines can never be eaten. The rest may be used as a protein source.

It is believed that this tortoise was the first animal on earth, that it is the most intelligent of all animals, and that it may even lie cleverly on occasion.

There are three major remedies which incorporate tortoise parts. The first is for cholera (Yoruba = "onigba meji"). The emetic is a combination of the head and intestines of the tortoise combined with an unidentified leaf (Yoruba = "erjin olubi onsowo") and the seed of the pepper, *Piper guineense* (Yoruba = "iyere"). These ingredients are individually burned to ash and then ground together. This mixture is stored in a small gourd having resealable openings in both the narrow top and wide bottom. When needed the ashes are mixed with a corn starch pap and given to the cholera victim orally. If the patient has symptoms of diarrhea, the ashes are removed from the opening in the bottom of the gourd. If vomiting is occurring, ashes are taken from the top opening of the gourd.

Turtle parts are also used to treat burns. The carapace is removed and broken into

pieces which are placed in a clay pot and heated to ash. These ashes are saved and sprinkled on burns, which are then said to heal within three days.

A third use of the turtle is as a preventative against the death of "evil children." If a child is born of parents for whom infant death is frequent, it can be taken to the Babalawo and diagnosed. If it is said to be an "evil child," this means the child would die within a week. The child is apparently "evil" since its death will be costly to the parents. As a preventative the claws and head of a tortoise are burned together with a leaf. (Yoruba for the leaf is "ayo," but depending on the emphasis 'ayo' is *Holoptelea grandis*, and ayo' is *Caesalpinia bonduc*.)

Crocodilus sp. and *Osteolaemus tetraspis* are apparently not used in medical practices, but skins are used for handbags and other leather goods. *Trionyx* sp. is used for food.

There are virtually no data concerning the population status of any of the reptiles discussed here; therefore no attempt to assess the impact of their usage can be made. It is impractical to expect that these uses could be controlled in the near future, and indeed, attempts to institute control border on the inhumane, since these animals are an important source of protein. In view of Nigeria's expanding human population, it seems imperative that more effort be exerted to ascertain the population status of these and other reptiles and that the impact of human activities on these animals be determined.

ACKNOWLEDGMENTS

We thank Rachel Falade for sharing this information with us. Our thanks also go to Dr. Joyce Lowe of the Ibadan University Botany Department for translating various Yoruba plant names into English and Latin. And we thank Dr. C. J. McCoy of the Carnegie Museum, and Dr. Thomas Turner and Joseph Brumble of Wheeling College for their constructive comments on the original manuscript.

COMMENT: SEXUALLY DIMORPHIC PLASTRAL KINESIS — THE FORGOTTEN PAPERS

The June 1984 issue of *Herp. Review* carried an article by G. N. Waagen describing sexually dimorphic plastral kinesis in *Heosemys spinosa*. Over the last two decades at least two significant papers (McDowell 1964; Bramble 1974) had reported that the plastron of *Heosemys* was akinetic. Bramble further reported, however, that the *Heosemys* examined by him had reduced plastral buttresses and at least a degree of the muscle specialization found in the kinetic *Cyclemys* group. None of these authors appear to have been aware of two earlier papers by the late Robert Mertens (1942, 1971) on the subject

It was Mertens (1942) who first described the post-maturational development of a partial hinge and the erosion of the bony connection between hypoplastron and carapace in female *H. spinosa*. Mertens (1971) reviewed the development of plastral kinesis in this species and used the characteristic to support his contention that the genera *Cyclemys* and *Heosemys* should be lumped (excluding *leytensis* and *silvatica*). At least one recent author has followed this recommendation (Lorenz 1984).

In turn Mertens (1942) appeared unaware of a still earlier report of sexual dimorphic kinesis. Anderson (1878) observed that females of *Melanochelys tricarinata* (but not males) have a ligamentous rather than bony connection between the hypoplastron and carapace. Smith (1931) repeated Anderson's observation and mentioned that in one old female examined, the hyo-hypoplastral union was clearly visible externally. While in India recently, I had the opportunity to verify Anderson's observations on living *M. tricarinata* and to add still another example of sexual dimorphic kinesis. Female cane turtles *(H. silvatica)* of southwestern India similarly develop a ligamentous connection between hypoplastron and carapace at maturity whereas in males the connection remains a bony suture. Since species showing this phenomenon lay large brittle-shelled eggs, the adaptive significance of a kinetic plastron is most likely to allow their passage from the cloaca (Mertens 1941; Waagen 1984) with only minimal reduction of the shell's protective function.

Inasmuch as a ligamentous connection between plastron and carapace may not be overtly obvious and only occurs in one sex, it is quite possible that the phenomenon is still more widespread. Persons having access to collections of batagurines should examine the small terrestrial-to-semiaquatic species with this in mind.

A NORTHERN NESTING RECORD FOR THE HAWKSBILL TURTLE

The hawksbill turtle *(Eretmochelys imbricata)* is a tropical coral reef/rocky shore-associating species that nests rarely on Florida beaches. Two nesting records are documented for Palm Beach County (Carr, Hirth, and Ogren 1966; Lund 1978), and additional unpublished nesting records exist for Martin County and elsewhere in extreme southern Florida (P. C. H. Pritchard, pers. comm.). This note reports an adult female hawksbill photographed at 0400 hr, 16 August 1982, while laying eggs at Canaveral National Seashore (CNS), Volusia County, Florida, thereby establishing a new northern limit for the hawksbill nesting range in the continental United States.

The previously untagged CNS animal was given two yellow Rototags (FL1951, FL1953) and a monel tag (AAK973) on the trailing edge of the front flippers. Over-the-curve carapace length was 84 cm. The clutch of 125 eggs was partially depredated (25% loss) by raccoons at the time of laying. Protective screening placed over the nest cavity prevented further predation, but the remaining eggs did not develop. The propensity for sea turtle eggs from raccoon-depredated nests to fail has been shown for loggerheads (McMurtray 1983) and may account for the hawksbill clutch failure.

THE DISTRIBUTION AND STATUS OF *Cryptobranchus Alleganiensis* IN MARYLAND

Cryptobranchus alleganiensis is listed as endangered in Maryland and is declining throughout its range (Williams et al. 1981a; Gates et al. in press). In Maryland, it is known from: 1) the lower Youghiogheny River, 2) the Casselman River, and 3) the Susquehanna River and its tributaries (Fowler 1915; McCauley and East 1940; Meszoely 1966; Harris 1975). There are unsubstantiated accounts from fishermen of *C. alleganiensis* in the Potomac River and tributaries, where it may have dispersed from the Youghiogheny via stream capture (Hendricks et al. 1983). An extinct Pleistocene form of *Cryptobranchus* is known from the Potomac River watershed (Holman 1977). This study's objective was to determine the present distribution and status of *C. alleganiensis* in Maryland.

From 30 September 1979 through 21 November 1981, approximately six days per month (range = 1-18) were spent surveying the Youghiogheny, Susquehanna, and Potomac rivers and tributaries, depending on weather and stream conditions. Several rivers emptying into the northern Chesapeake Bay were also included, as well as the mouths of tributaries of the Potomac River in nearby West Virginia and Virginia (Fig. 1). No surveys were done from December through March. Most survey days (92.6%) occurred from May through October. Although several different techniques were employed in stream surveys (see Williams et al. 1981b), electrofishing with dip nets was the one method used most often by the survey crew. A two-to-four man crew spent 308.5 in-stream hours (905.5 man-hours) sampling for *C. alleganiensis*. Two hundred and fifty-nine individual sites were sampled: 91 in the Youghiogheny River system, 44 in the Susquehanna River system and other streams emptying into the northern Chesapeake Bay, and 124 in the Potomac River system (Fig. 1). Multiple samples were often made where habitat appeared good. Twenty-four percent of the sites were sampled both day and night. Night sampling usually began about 0.5 hour after sunset. We spent an average of 54 (± 2.3 SE, range = 15-300) minutes per sample. All captured individuals were returned alive to the stream.

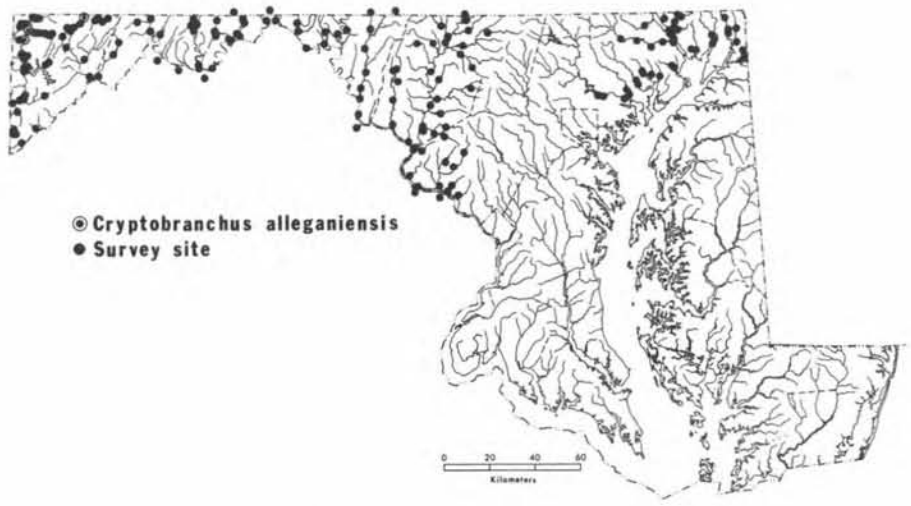

Figure 1. Location of sites surveyed for *C. alleganiensis* in Maryland.

Additionally, 200 "hellbender wanted" posters were posted along the Youghiogheny and Susquehanna river drainages, Gunpowder Falls, and Little Gunpowder Falls between 31 March and 7 May 1982. On 1-2 May 1983, 42 additional posters were placed along the Susquehanna River and its tributaries. No posters were placed along the Potomac River drainage.

Between 29 May 1980 and 30 September 1982, seven *C. alleganiensis* were captured within a one kilometer section of the Casselman River from 1.6 km north of Crab Run Road to 0.8 km south of the Pennsylvania state line (Fig. 1). Individuals ranged from 298-438 mm total length (212-270mm snout-vent length) and weighed from 245-530 g. Our stream surveys were unsuccessful in locating *C. alleganiensis* elsewhere in the Youghiogheny River system, or in the Susquehanna and Potomac River drainages.

We received ten responses to our "hellbender wanted" posters. Three resulted in documentation of *C. alleganiensis* in Maryland streams. One fisherman hooked and caught a *C. alleganiensis* in the Casselman River on 13 April 1982 near the sites already identified by our stream surveys. Another fisherman caught and photographed a *C. alleganiensis* in the Youghiogheny River at Friendsville, Maryland, on 15 April 1982 approximately 274-366 m upstream of the confluence with Bear Creek (Fig. 1). This was the first record we had of *C. alleganiensis* in the Youghiogheny River system, other than the Casselman River, since we began our study. On 22 August 1982, another *C. alleganiensis* was captured, photographed, and released by Drew Ferrier, a biologist with Garrett Community College, McHenry, Maryland, while electrofishing 2.4 km south of Friendsville (Fig. 1). These two records from the Youghiogheny River document the continued presence of *C. alleganiensis* in a 4.0 km section. No response was received from fishermen along the Susquehanna River or any of its tributaries.

Compared with our previous work in Pennsylvania (Williams et al. 1981b), *C. alleganiensis* populations in the Youghiogheny River system in Maryland are sparse. The Casselman River probably has a more dense population than the Youghiogheny River. *Cryptobranchus alleganiensis* is highly susceptible to pollution and the submergence of swift water riffles by artificial impoundments (Gentry 1955; Nickerson and Mays 1973). The Youghiogheny River Reservoir just north of Friendsville eliminated much *C. alleganiensis* habitat and is a definite barrier to dispersal. Acid mine drainage, municipal sewage, industrial effluents, agricultural runoff, and siltation resulting from forestry practices, mining, and construction are the major pollutants in the Youghiogheny River system. The most limiting pollutants to aquatic organisms in this system are acid mine drainage and siltation (Hendricks et al. 1983). The river was considered almost lifeless in 1950 (Reppert 1964). The decrease in coal production and the increase in water quality law enforcement and mine drainage abatement projects since then have improved water quality considerably.

The lack of recent information from the Maryland portion of the Susquehanna River system leaves the continued existence of *C.*

alleganiensis there in doubt. The Conowingo Reservoir eliminated much habitat and is a definite barrier to dispersal. The same pollutants found in the Youghiogheny River system, excluding possibly acid mine drainage, are factors that may have affected populations here. Low dissolved oxygen concentrations and nutrient enrichment are two of the concerns in the Susquehanna below Conowingo Dam (Rudisill 1979). However, several tributaries of the Susquehanna, especially Deer and Octoraro creeks, appear to be suitable habitat. Even in these two streams, elevated nutrient concentrations and siltation are problems (Rudisill 1979).

There is no evidence of the occurrence of *C. alleganiensis* in the Potomac River system. Water quality in the Potomac River basin ranges from poor in the North Branch, where acid mine drainage restricts most aquatic life, to good from the confluence of the North and South branches downstream to Little Falls Dam, Maryland. Nutrients, bacteria, and sediment from inadequately treated municipal sewage discharges and street and farmland runoff are the major forms of pollution in most of the Potomac River basin (Mason et al. 1976).

Cryptobranchus alleganiensis in Maryland is rightfully categorized as endangered. Where it is found, populations appear to be low. We found no evidence of successful reproduction though we sampled during the late summer-fall breeding season. Besides different forms of pollution, fishing could have an impact on populations. Many fishermen believe that *C. alleganiensis* is poisonous and attempt to kill captured individuals before removing them from the hook. Or, they may merely cut their line and release them with the hook imbedded inside their digestive tract (Nickerson and Mays 1973). Mortality from this impact is difficult to document, but could be considerable in certain areas. Better education of the fishing public would be an important means of reducing this source of mortality.

ACKNOWLEDGMENTS

We thank Clark Shiffer, Pennsylvania Fish Commission, for his help in the early stages of the study, and Bob Davis, Maryland Water Resources Administration, for information on water quality in Maryland streams. Several people contributed time and muscle as members of the survey crew. Thanks go to Dave Williams, Carl Christianson, Ed Esmond, Paul McKeown, Dave Oswald, Ron Stouffer, Tim Welch, Jim Lebo, Terry Barila, Rich Raesly, and Brian Lang. Typing was done by Evelyn Kirk. Funds for this research were provided by the Maryland Department of Natural Resources, Forest, Park, and Wildlife Service, and the U.S. Fish and Wildlife Service, through the Maryland Endangered Species Program. This is Contribution No. 1550-AEL, Center for Environmental and Estuarine Studies, University of Maryland.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoo, Box 6040, Knoxville, Tennessee 37914, U.S.A.

EGGS AND HATCHLINGS OF THE YELLOW GIANT CHUCKWALLA AND THE BLACK GIANT CHUCKWALLA IN CAPTIVITY

Iguanid lizards of the genus *Sauromalus* (chuckwallas) are found only in the Southwestern United States, and in Northern Mexico. They are thought to have originated from *Ctenosaura* (spiny-tailed iguana) stock (Etheridge 1964; Hotton 1955; Smith 1946; Mittleman 1942). There are eleven subspecies, six belonging to the fine scaled "*obesus* group," and five belonging to the rough scaled, "*atar* group" (Robinson 1972). Three subspecies are in the United States, one on Baja California, one on the Mexican mainland, and six on the islands in the Gulf of California, Mexico (Shaw 1945).

Gigantism has evolved in two of the insular species. *S. varius* belongs to the "fine scaled group" while *S. hispidus*, belongs to the "rough scaled group." Both species are confined to the Midriff islands and are allopatric except for a small population on Isla Alcatraz. This island has both yellow and black giant chuckwallas. They have been introduced by Mexican fishermen and Seri Indians, respectively (Moser, per. com.). Natural hybridization has occurred there between the two giant forms, and betwen the giant and mainland species. Fertile hybrids have been produced from these crosses (Lowe et al. unpub. ms.).

From 1974 through 1983 I witnessed the gradual deterioration of the flora and fauna of the Gulf of California. Recently some effort has been made to prevent this trend from affecting giant chuckwalla populations.

In the past these rare lizards have been removed for sale to the pet industry, and in the process much destruction has been done to their native habitat. This destruction is a direct result of the careless use of crowbars, picks, and shovels as the collectors chased the lizards down and dug them out of their caves and burrows. On 19 April 1980, *S. varius* was placed on the endangered species list (U.S. Fish and Wildlife Service 1980). While helpful, enforcement of this decree is not an easy task and is not likely to completely resolve the problem. Additional management of giant chuckwallas, especially *S. varius*, will be imperative if these animals are to survive.

Chuckwallas raised in captivity could be used to satisfy the demands of the pet industry, and at the same time be introduced as hatchlings, juveniles, or adults, to sustain declining island populations, or to develop new populations outside of their native island habitat.

This study focused on the eggs and hatchlings of the two insular giant forms. The eggs and hatchlings of *S. varius* are described for the first time. Eggs and hatchlings from a cross of a yellow giant female and a black giant male were successfully hatched and reared.

METHODS

In November of 1974, two male and two female *S. varius* were brought from San Esteban Island, Gulf of California, Mexico (Mexican Permit No. 203274-9 Series), to an outdoor enclosure in Tucson, Arizona. One year later a male and female *S. hispidus* were added to the enclosure. The elevation of the study area is 823 m, which is well within the elevation of their island habitat (maximum elevation 1316 m). The humidity, however, is usually much lower in Arizona; and the temperature extremes ranged from -1° C to +45° C during the study period vs. +8° C to +43° C on the islands (based on data from 1974 to 1980).

The natural clay soil in the enclosure was covered with 46 cm of desert wash sand. The enclosure size was (6.7 x 5.8 x 1.2 m), with plastered walls so that the lizards could not climb out. At the center of the enclosure was a black, artificial rock (2.5 x 1.8 x 1 m). It was constructed from concrete reinforcing rods, wire mesh, and black pigmented cement. The rock's surface was slanted toward the south so that it could absorb a maximum amount of sunlight throughout the day.

Trenches 50 cm and 30 cm deep were dug along the inside of the west and south walls of the enclosure and were covered with 7 mm thick plastic sheets. The plastic sheets were elevated from the ground by using concrete topping blocks (2.5 cm thick). The space between the sheets and the sand made it possible for the lizards to move in and out of the trenches at will. The translucent nature of the sheets also made it possible to grow sunflower seedlings (greenhouse fashion) in the trench soil. These seedlings provided a source of water and nutrition throughout the year. In addition, this system allowed most light rays, excluding ultraviolet, to reach lizards basking under the plastic sheets.

Outside the enclosure walls was a 15 cm thick, 5 m wide concrete skirt. The skirt provided a solid, escape-proof ceiling, that allowed the lizards to dig under the walls and hollow out deep dens. This was one of their preferred places to congregate during both summer and winter seasons. The plastic sheets protected the den areas from wind, rain, and predators.

The artificial rock and trenches were heated in the winter by electric forced air heaters (1000 watts) with plastic casings that prevented the lizards from burning themselves; the artificial rock was sprayed with water from a drip hose during the hottest part of the summer days (1300 to 1500 hr.) to avoid temperatures beyond the tolerance of these lizards. The summer temperature extremes in the non-irrigated parts of the enclosure reached 45° C, while in the winter the outside temperature dropped to -1° C. The temperatures were recorded in the shade within the enclosure. This low temperature never reached the lizards in the artificial rock or trenches, (monitored by maximum-minimum thermometers) which maintained a minimum temperature of 21° C. This system was vital in order to maintain proper soil moisture for egg incubation, to prevent extreme temperature build-ups during the hot summer months, and as a guard against freezing temperatures during the winter.

Hatchlings from the outdoor enclosure were raised indoors in terrariums (2 x 1 x 0.7 m), with 10 hatchlings per terrarium. They were given two hours of sunlamp exposure every other day. The sunlamp was mounted 1.5 m above the terrarium's surface. The terrariums were provided with a 250 watt, infrared light and two heating pads maintained at 30° C. The infrared light was mounted 46 cm above two concrete blocks that were set on end. This provided a natural basking site with a temperature of 38° C. The room was maintained at 25° C. Thus, the hatchlings had three temperatures that they could choose from: 25° C, 30° C, and 38° C. The photoperiod was from 0700 to 1900 hr.

Food Regime

Adult chuckwallas were offered fresh carrot slices, chopped lettuce and several genera of native plants that were known to be eaten by *S. obesus* (Hansen 1974; Nagy 1973; Sanborn 1972) and giant chuckwallas (personal observation). Some of these plants are as follows: *Sphaeralcea ambigua, Baileya multiradiata, Erodium cicutarium,* and the fruit of *Opuntia engelmannii.*

Hatchlings were fed flats of fresh sunflower seedlings and a mixture containing 90 g of shredded carrots (fresh weight) and 10 g of finely ground chick starter (air dry weight). This mixture is readily eaten by the hatchlings, and is excellent nutritionally, providing 20% protein, 3% fat, 6% fiber, and Vitamin D_3 for bone growth.

Hatchlings were always fed on a clean, non-sandy surface. Failure to do so resulted in hatchling deaths due to the ingestion of small rocks. Adult chuckwallas normally ingest and pass small rocks through their digestive tract and for this reason, less care was needed during their feeding times.

RESULTS AND DISCUSSION

On 12 September 1977, 23 *S. varius* hatchlings were discovered in the outdoor enclosure. They had crawled through the drain hole of a metal sink that had been turned upside down on the sand surface of the enclosure. The sink had been checked three days prior to finding them, and was empty at that time, so they must have entered the sink between September 9th and 12th. The average mass and SVL of the hatchlings were 14 g (s = 0.44) and 71 mm (s = 1.3), respectively. Before reaching adult size, giant chuckwalla hatchlings increase their mass by a factor of at least 60 (14 g to 900 g), and their SVL by a factor of at least four (71 mm to 300 mm). Four days later a second group of hatchlings was found in the enclosure (average mass = 13 g, s = 0.17; SVL = 71 mm, s = 1.3). The mass and SVL of the second group was not significantly different from those of the first group (P = 0.01). A search was made of the enclosure, but no egg clutches were found.

On 26 September 1977 a tunnel was found in the enclosure. The female had entered the artificial rock and had dug beneath the sand in an easterly direction. The tunnel continued east for approximately 61 cm and then branched into two tunnels, one going south and the other going north. The branched tunnels were equal in length and extended for 30 cm beyond the fork. The eggs were buried approximately 38 cm beneath the surface. The north branch contained 18 unbroken shrunken and wrinkled egg shells. The eggs appeared old and were riddled with dozens of small holes (about 1 mm in diameter) that appeared to have been made by insects. From these observations I concluded that the eggs had been laid the previous year. The south branch contained 19 eggs, four of them empty and their hatchlings alive in the tunnel, attached to their egg sacs. The remaining 15 eggs were incubated indoors, in the dark, within a styrofoam ice chest. The eggs were placed on a wire screen that was mounted above the water. The eggs were incubated at 32° C using an aquarium water heater with thermostatic control; but none of them hatched. When opened they were found to contain embryos at different stages of development. The clay soil in this part of the enclosure was very hard and may have had a below normal oxygen tension that prevented all but the

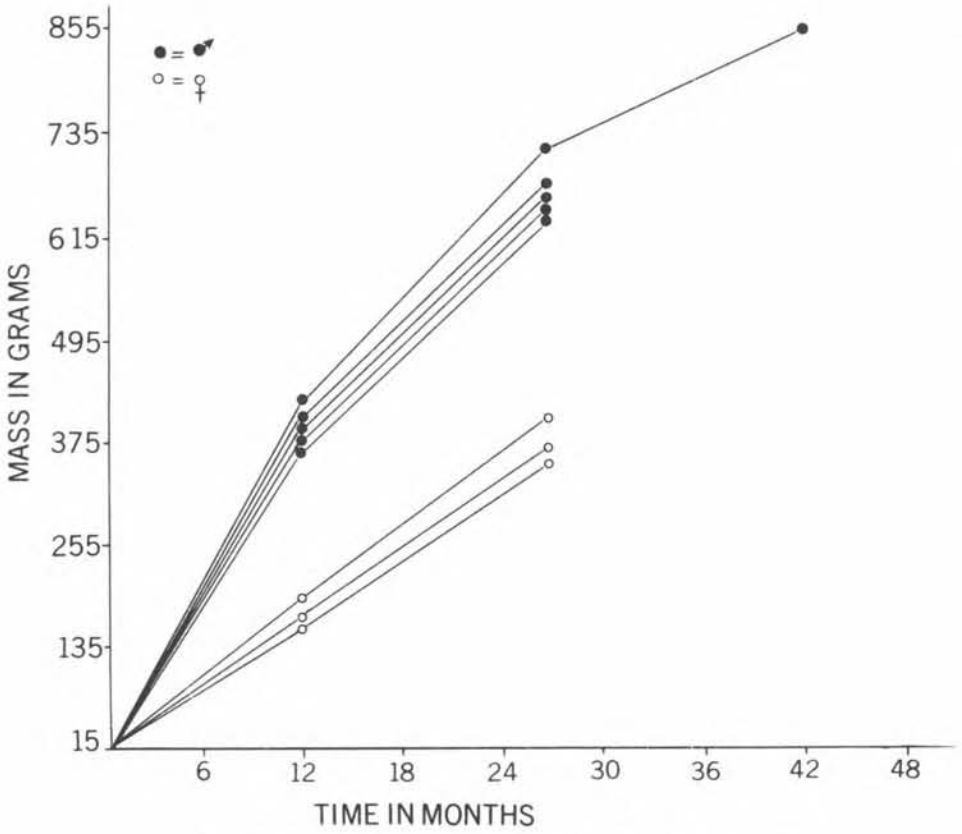

Figure 1. Increase in mass of 8 *Sauromalus varius* hatchlings.

hardiest embryos from hatching. It is also possible that the egg clutch became partially submerged in water at some time during the incubation period, although no evidence of water was present at the time the egg clutch was discovered.

The four hatchlings that were found alive in the south branch of the tunnel did not have the 1 mm spots that are characteristic of *S. varius* hatchlings, but instead had a mosaic pattern and banding of the body and tail which was similar to Schmidt's description of *S. hispidus* hatchlings (Schmidt 1922). The identity of the hatchlings was confirmed when, at the end of three months, the bands disappeared and the ground color turned from the mosaic pattern to solid black, a transition found only in *S. hispidus*.

In the spring of 1978 a portion of the enclosure was partitioned off and a yellow female giant chuckwalla introduced along with a black male giant chuckwalla. On 8 September 1978, 12 hatchlings were found in that part of the enclosure. They had sand and clay stuck to their snouts and were either dragging their egg sacs or had just broken free from them, as evidenced by the trailing abdominal cords. The appearance of these hatchlings was very similar to those of *S. hispidus*. It was not until 3 months later, when the mosaic pattern and rings faded, that the hatchlings could be positively identified as hybrids (Lowe et al. unpub. ms.). Instead of the mosaic pattern and rings being replaced by a solid black ground color, as is the case with *S. hispidus*, the ground color remained light brown and the typical black, irregular blotches of *S. varius* began to appear. The scalation of the hybrid is similar to the coarse scalation of *S. hispidus*.

From 12 September 1977 to 13 September 1979, 90 hatchlings were raised in captivity (Table 1). Ten of the 23 hatchlings from the September 12th clutch were selected at random, and their masses and SVLs monitored for a period of 27 months (two of the hatchlings died within 10 days so eight were actually used). Three of the remaining lizards were females, and grew at a slower rate than the five male lizards (Fig. 1). The hatchlings were kept in a large terrarium (2 x 1 x 0.7 m) and were measured at 12 and 27 months. On the average the males outgrew the females by a ratio of 1.9 to 1 when their masses were compared, and 1.7 to 1 when SVLs were compared. When the means of these classes were compared at 12 and 27 months the male and female lizards were found to be significantly different in both their mass and SVL growth patterns. (Table 2). One of the hatchlings, the tyrant, was followed to full adult size (mass = 900 g; SVL = 300 mm). He reached this limit at 42 months. When the mean growth of the tyrant was compared to that of the subordinate males and females, a significant difference was observed ($t = 3.24$, $P = 0.05$; $t = 13.98$, $P = 0.01$, respectively). Their masses and SVLs at hatching were compared and found not to be significantly different (Mendenhall 1975; Snedecor and Cochran 1976). The exact time that a significant difference between male and female growth occurred was not determined, but sexing of males and females may be possible as early as two months after the hatchlings emerge from their eggs.

During the three seasons from 1977 to 1979, 37 *S. varius* eggs and 19 *S. hispidus* eggs were collected and measured. The mean size of the yellow giant chuckwalla eggs was 35 mm (s = 0.82) x 50 mm (s = 1.01). The black giant chuckwalla eggs were not found to be significantly different in size from those of the yellow subspecies ($P = 0.01$). Using the formula $V = 4/3\ \pi\ ab^2$ (Oberg et al. 1975) the mean volume of the *S. varius* and *S. hispidus* eggs was determined to be 32 ml ($n = 25$; $s = 2.16$). No significant difference was found between the volume of yellow and black giant chuckwalla eggs ($P = 0.01$). This compares to 11 ml for *S. obesus* eggs (Prieto and Sorenson 1977; $n = 24$). The fact that giant chuckwalla eggs are nearly three times the volume of *S. obesus* eggs, should allow them to survive more extreme temperature variations than those of *S. obesus*, due to the smaller surface to volume ratio of their egg surfaces (Gordon 1977). This larger ratio would allow giant chuckwalla eggs to survive short periods of unfavorable temperature changes to a greater extent than eggs of smaller species. (Muth 1980). At the same time, the larger egg has a slower metabolic rate and will require a longer incubation period, which increases the chances for exposure to extremes of soil temperatures (Gordon 1977).

Muth (1980) described an incubation period of 40 to 90 days for the eggs of the desert iguana *(Dipsosaurus dorsalis)*. He proposed successful incubation temperatures between 28° C and 36° C. Eggs incubated at 28° C took 86 days to hatch, while those at 36° C required only 44 days to hatch. Water potentials between -50 and -1500 kPa did not significantly affect incubation time, but he also reported that water potentials at -1500 kPa

caused 20% of the hatchlings to be deformed, and at -2000 kPa, 50% of the hatchlings were deformed. These two parameters are no doubt responsible for incubation time differences in the chuckwalla eggs.

Carl and Jones (1979) incubated black giant chuckwalla eggs in a sealed aquarium and maintained a temperature between 29° C and 31° C. This was at the lower temperature tolerance of egg incubation (Muth 1980) and resulted in an incubation period between 94 and 99 days. The shorter incubation period required for my eggs in the enclosure probably reflects soil temperature levels that were higher (34° C to 36° C) and represents a temperature profile that is near the optimum required for egg incubation (Muth 1980).

Carl and Jones (1979) found their black giant chuckwalla eggs to be considerably smaller than mine, having a mean size of 29 x 44 mm and a volume of 19 ml. The discrepancy between the two egg volumes may be due to the use of smaller females by Carl and Jones (Vitt 1977). Another possibility may have been the differential absorption of water under different soil moisture conditions.

Description of Hatchlings

Sauromalus varius: The ground color on both the dorsal and ventral surfaces was tan, peppered with black, 1 mm spots found on all parts of the body, including the legs, arms, and tail. Only the head was free of these spots. On the dorsal surface the ground color and spots were interrupted by a yellow stripe that ran about 15 mm down the middorsal line on the nape of the neck. The posterior end of this stripe faded back into the tan ground color. As the middorsal line was followed to the tail, the ground color was interrupted by four to five yellow patches. No bands were present in this species. At approximately three months the 1 mm spots merged into black patches and the nape stripe began to fade.

Sauromalus hispidus: My description of *S. hispidus* hatchlings is in general agreement with that of Carl and Jones (1979). The dorsal ground color was brown but the mosaic pattern of the scales that divide the ground color appeared to be white in my hatchlings (they use the term reticulum rather than mosaic). The head was gray. Four transverse bands crossed the dorsum and a fifth was found at the nape. The tail usually had four bands, but occasionally five or six bands were observed.

Near the middorsal line the ground color was tinged with yellow and orange scales that formed a narrow stripe that began at the posterior edge of the nape band and ended at the proximal edge of the fourth dorsal band. As in yellow giant hatchlings, there were distinct color changes at the end of three months: the ground color became much darker, the mosaic pattern disappeared, and the yellow-orange middorsal line began to fade. I also observed the black bars that extend from the eyes to the tympanic cavity; these bars tended to give the lizards a raccoon-like appearance when viewed from the side. *S. hispidus* hatchlings exhibited an ability to change color under high light intensities and temperature elevation that was not as apparent in *S. varius* hatchlings. In bright sunlight the hatchlings turned almost black, and completely lost their mosaic pattern. After 20 minutes in the shade the mosaic pattern returned. The parietal eye, which is thought to function in thermoregulation and in reproductive activities (Ralph 1975; Ralph et al. 1979) was clearly seen in both *S. hispidus* and *S. varius* hatchlings.

ACKNOWLEDGMENTS

I am indebted to Dr. Richard M. Hansen for his support and assistance throughout this study. Special thanks to Dr. Reid Moran for his time and effort in reviewing this paper. My sincere thanks to the Government of Mexico, and to the office of The Direccion De La Fauna Silvestre, for the privilege of carrying out research studies on the islands in the mid-riff region of the Gulf of California, Mexico.

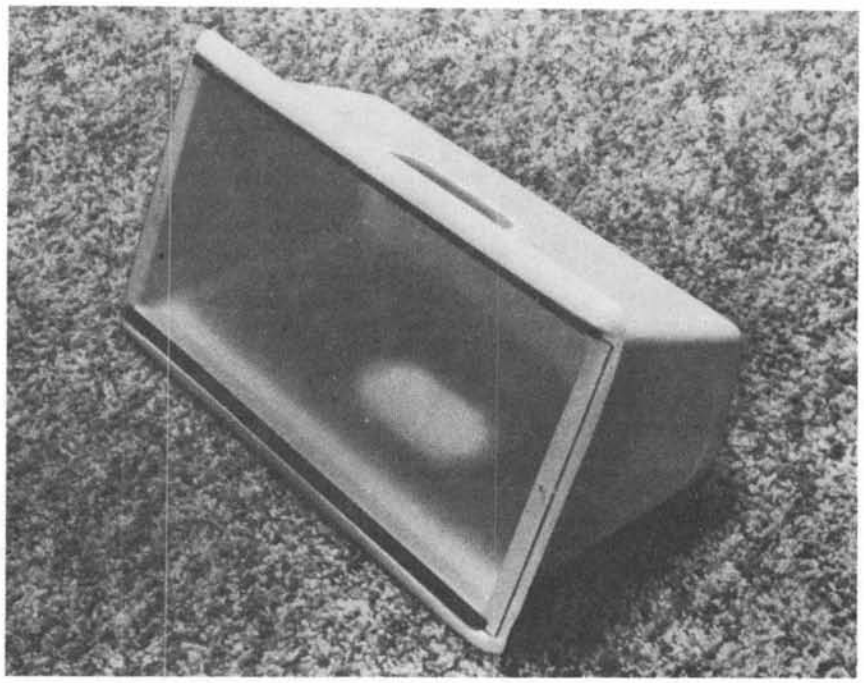
ADDITIONAL NOTES ON THE BREEDING AND CAPTIVE MANAGEMENT OF THE PREHENSILE-TAILED SKINK *(Corucia zebrata)*



In 1975 I summarized observations on a group of captive *Corucia zebrata* (Honegger 1975). Since then, knowledge of this arboreal skink from the Solomon Islands (McCoy 1980) has increased considerably.

Origin of the specimens

The first specimens arrived in 1973 from the Bougainville Islands. In 1975 another shipment was received from the Island of Guadalcanal, also within the Solomon Islands. The largest female from Bougainville measured

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $29.95

24" Wide, 12¼" High, 12½" Deep
Approx. 250 sq. in. floor area
Single Vent

36" Reptile Cage $53.95

36" Wide, 18" High, 19" Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

A/C 316 325-3096

720 mm (SVL = 325, Tail = 395 mm) and weighed 758 g at its death after four years and one month in captivity. Our longevity record for imported specimens is seven years and 11 months for a female from Guadalcanal.

With the birth of twins on 23 December 1983 by the female (ZZ207) born 26 August 1978, [possibly mated with male (ZZ214) born 7 January 1981] we probably have a good F_1 generation of *C. zebrata* at Zurich Zoo.

Reproduction

Reproductive behavior was observed only once due to the crepuscular and nocturnal activity of the skinks.

After re-introduction of female ZZ207 four months after giving birth to ZZ219 and ZZ220 on 5 May 1984, copulation with male ZZ214 was observed at approximately 1200 hr.

The male followed the female on the ground for about three meters in the terrarium without tail movements. He approached the female when she was about to climb on a log, touching her with his tongue and licking her dorsally. Then the male started biting her on the left side of the neck while holding her on the trunk with his left front leg. The male then began to stroke the back and the pelvic region of the female with his left hind foot.

After a few moments, the female started raising her pelvic region and arched the tail slightly (Fig. 1). The male began twisting his pelvic region and cloaca, slid his tail slightly and achieved copulatory position. Copulation lasted for about seven and one half minutes. The female then started dragging away and began climbing the log. During copulation the prehensile tails were bent only slightly but not anchored.

Figure 1. *Corucia zebrata* in copulation (Foto Honegger)

From scars on the necks and pelvic regions of the females, we assume that reproductive activity always involves biting of the neck and stroking of the pelvic area by the male.

From close observation of individual females, we estimate a gestation period of approximately six months.

Since we lost two neonates by adult cannibalism, we now separate gravid females into medium sized terraria (100 x 50 x 90 cm) with adequate cover (leaves, peat moss, branches, bark, hollow logs, etc.). To determine the status of gravid individuals, the specimens are x-rayed (Fig. 2).

Figure 2. X-ray of female *Corucia zebrata* ZZ207 nine days prior to parturition. (X-ray and foto Zoo Zurich)

Between August 1973 and April 1984, 21 *Corucia zebrata* were born at Zurich Zoo. All but three births occurred during the night. Nine births were single, six were twin specimens, and seven specimens were stillborn. In each case, the birth membranes were eaten, probably by the females. Hitz (1983) made similar observations with *Trachydosaurus rugosus*.

Management

Immediately after birth, the neonates tended to hide within leaves, bark, or in hollow logs. The females and young were then very aggressive, as both followed and bit the intruder trying to separate them. The young were raised in separate terraria with adequate cover. After shedding their skin within 9-11 days, the young began feeding.

The females were also kept separately from the group for several weeks, allowing sufficient time to recover. After parturition, the females received an injection of vitamins A, D, E and Voren®, according to their weight. This precaution, applied to all female reptiles in the zoo after giving birth or egg laying, proved to be very successful to avoid unnecessary loss due to exhaustion.

The food consisted of fresh vegetables, including beans, carrots, fresh fruits (including kiwis), and minced meat, offered three times a week. It was supplemented with calcium, vitamins (Vionate®) and crushed dry shrimps. Bay mice were never and locusts rarely accepted. As mentioned in the earlier paper (Honegger 1975), leaves and branches of *Monstera* and *Scindapsus* were immediately accepted by the skinks. Coprophagy and keratophagy were normal behavior in adults and young.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

ANURA

BUFO MARINUS (Marine Toad). **ANOMALY.** *Bufo marinus* was found dead on 13 April 1983 in the Komohana Gardens Subdivision bordering Waiakea Stream in Hilo, on the Island of Hawaii. The toad was a young male, measuring 85 mm body length and appeared emaciated. It lacked its left hind leg. The stomach and cloaca contained a single long-legged ant, *Anoplolepsis longipes*, and a

large amount of ingested soil. Other toads caught in the area had a greater variety of insects in their gut and little, if any, ingested soil. These observations suggest that our specimen was handicapped in feeding and had taken advantage of the most abundant food item available. We surmise that the toad had been foraging the previous night and was caught in the morning heat unable to return to shelter. The site of the find was a concrete sidewalk bordered by a long stonewall and a broad roadway. The nearest vegetation which might have provided shelter was about 7.5 m away.

Initial examination showed no obvious wound or scar tissue at the site of the missing leg (Figure 1). Radiographs showed no remnant of a femur attached to the acetabulum (Figure 2). The pelvic girdle and lower vertebral column was noticeably rotated to the left.

There appeared to be a healed fracture of the right femur. The distorted pelvic girdle and bone fracture were probably the result of the stress brought on by moving about with a single hind leg. The evidence suggests that the leg loss was a longstanding condition and may have been due to a congenital defect or injury at an early stage of larval development.

This specimen is in the University of Hawaii at Hilo's vertebrate collection and will be deposited with the Bishop Museum, Honolulu, Hawaii.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). **REPRODUCTION.** Reproduction in the western chorus frog has not been intensively studied and data thus far consist of casual observations. Collins (1982. Amphibians and Reptiles in Kansas 2nd edition) stated that females of this species may lay from 100 to 1500 eggs in small clutches of 20 to 30 on submerged plant stems and hatching occurs in about two weeks. The following observations serve to augment the reproductive data of this species and were made while conducting a herpetofaunal survey on Konza Prairie Research Natural Area (KPRNA) south of Manhattan in the Flint Hills region of Kansas.

On the morning of 14 March 1983 a male (1.5 g, 25 mm SVL) and female (1.5 g, 24 mm SVL) *P. t. triseriata* were collected from a temporary KPRNA spring-fed, grassland stream and placed along with water and dead grass into a glass jar. Upon returning to the lab that afternoon, the frogs were in amplexus and the female was in the process of laying eggs. A total of 294 eggs was deposited on the grass substrate in four masses of 5, 22, 110, and 157. The female weighed 1.0 g after laying the eggs. The eggs along with grass substrate were placed in a 38 l (10 gal) aquarium containing approximately 9 cm of water. Lettuce was also placed in the aquarium as a feeding substrate for tadpoles. The water was aerated and ranged in temperature from 17° to 25°C with a mean of 21°C. Tadpoles hatched from 19-22 March. Twenty tadpoles hatched; the remaining eggs appeared infertile and soon deteriorated. On 14 April 15 tadpoles were yet alive and three of those were preserved on 20 April. On 29 April small appendages were apparent on tadpoles. By 25 May, four had completely metamorphosed and others were in the last stages of metamorphosis. All were preserved on 26 May.

On 25 May 1983 at 1350 hr an amplexing pair of *P. t. triseriata* was found in a woodland KPRNA stream. No eggs were around the pair so it was assumed that deposition of eggs had not occurred. The frogs were placed in a damp cloth bag and 8 hours later upon removal from the bag the frogs were still in amplexus. They were placed in a glass bowl with grass substrate and the female laid four clumps of eggs containing nine, 25, 46 and 143 eggs for a total clutch size of 223. These eggs were promptly preserved after deposition.

SCAPHIOPUS INTERMONTANUS (Great Basin Spadefoot Toad). **MORTALITY.** Larvae were found in a shallow pond 9 km SW Barriere, British Columbia, Canada on 7 July 1984. Growth and development of the larvae were monitored over the following three weeks (Table 1). Samples of larvae were collected and preserved in 10% formalin.

During hot dry weather the pond began to dry and larvae were surfacing for air and then diving to the bottom. On 15 July common crows *(Corvus brachyrhynchos)* were observed catching and eating the larvae. An adult crow stood at the pond's edge, waited, then plunged its beak into the shallow water. In one 10 minute period it captured five larvae. The adult crow was accompanied by four young. They did not attempt to catch larvae although one young crow stood poised at the water's edge but did not strike. On several occasions the adult fed larvae to the begging young. After hunting and feeding on toad larvae for about 20 minutes the crows moved to a nearby pasture and fed on worms and insects. Crows visited the pond and captured larvae at various times until 21 July.

Most of the larvae were transformed by this date and had only remnants of their tails. It rained lightly in the late afternoon of 21 July, but heavily that night during a thunderstorm. By morning only a few larvae remained in the pond. These were less developed than the bulk of the larvae present the day before. Some had only begun to grow legs. This storm, the only precipitation in nine days, may have facilitated dispersal of the toads. Small toads were captured 110 m from the pond on 2, 4, and 7 August along a dry south-facing sidehill. If these small toads were among those that dispersed from the pond since 17 July, snout-vent length did not change, length of the hind leg increased and body weight decreased.

Submitted by **ALTON S. HARESTAD,** Department of Biological Sciences, Simon Fraser University, Burnaby, British Columbia, Canada V6T 1W5. ●

FURMONT REPTILE EQUIPMENT

Professional Equipment For The Herpetologist

SINCE 1972

FUHRMAN DIVERSIFIED offers you the broadest line of Professional Equipment for the Herpetologist and Zoologist. We presently supply over 250 Zoos and Aquariums, 100 Universities, 100 other organizations and thousands of individuals with the finest equipment available. Your satisfaction is guaranteed. Order early for fastest delivery.

FURMONT REPTILE HOOKS
- 14 Styles and Sizes
- Fixed Length & Collapsible Handles
- Mini to Boa Sizes
- Genuine "Stump Rippers"

REPTILE BAG STIK**
- Reptile Capture Bag Holder
- **U.S. Patent #3872834

SUP-R-BAGS
- Rip Stop Nylon Collecting Bags

HIDING BOXES
- 3 Sizes, ABS Plastic

FLEXI-NETS
- Flexible Hand Nets for Turtles, Lizards, etc.
- 12″ to 30″ Dia., 6″ to 32′ Handles, 4 Styles

STREAMLITE HANDLIGHTS
- AC and DC Rechargeable
- Ultra-High Intensity Quartz Halogen
- Field and Emergency Lighting

SNAREM-PLUS
- Noose Pole, 3′ to 6′ Lengths

WHITCO TONGS
- Best Field Tong Available

REPTILE SEXING PROBES
- 5 Sizes, Surgical Stainless Steel, Field Case

ELAPID ENVENOMATION KIT
- Under Development

PROTECTIVE APRONS/GLOVES
- Under Development

Phone or Write for Additional Information or Catalog(s).

CAUDATA

AMBYSTOMA GRACILE GRACILE (Brown Salamander). **WINTER ACTIVITY.** On 5 January 1984, at 2120 hr, an adult male *Ambystoma gracile* was collected as it crossed a road at the Wind River Experimental Forest, 8 km N Carson, Skamania Co., Washington. The air temperature at time of capture was 1° C. Ten measurements of snow depth were taken at 3 m intervals on both the W and E sides of the road. On the W side was a small residential area. A large silviculture field on the E side of the road was completely exposed. The mean snow depth was 35.8 cm. The late fall and early winter months prior to capture were abnormally cold, with temperatures down to -22° C, and maximum December temperatures near freezing. On 3 January, temperatures warmed up, and a small, shallow reservoir of Trout Creek (185 m away) known to harbor *A. gracile* larvae, partially thawed. On 5 January the maximum air temperature was 5° C.

Nussbaum et al. (1983. Amphibians and reptiles of the Pacific Northwest, University Press of Idaho) indicate that terrestrial adults of *A. gracile* tend to be active only during warm spring and fall rains, especially during the spring breeding season. In winter and summer, they reportedly reside in subterranean retreats. The new record indicates that this species may have a longer period of yearly activity and a greater tolerance of cold temperatures than previously thought. This observation is one of a few records for temperate non-plethodontid salamanders found at a temperature near freezing (Feder and Lynch. 1982. Ecology. 63:1657-1664).

I thank J. Buchanan, R. Lundquist and D. Zirjacks for assistance gathering data, and R. B. Bury for commenting on the text. The specimen will be deposited in the National Museum of Natural History (USNM). Contribution number 15 of the Old Growth Wildlife Habitat Program, U.S. Forest Service.

Submitted by **LAWRENCE L. C. JONES,** Denver Wildlife Research Center, 1300 Blue Spruce Drive, Fort Collins, Colorado 80524, U.S.A. ●

DICAMPTODON ENSATUS (Pacific Giant Salamander). **COLORATION.** On 4 September 1983, an albino Pacific giant salamander was collected in a tributary of Panther Creek, 12.8 km N Carson, Skamania County, Washington. The larva was found in 3 mm of water under a 50 x 38 mm rock on a small island between two riffles of the creek. The water temperature was 7.5° C at the time of capture (1620 h). The salamander measured 38 mm SVL and 67 mm TL, and weighed 1.7 g.

The specimen is yellowish, with no indication of pigment. The end of the tail, which is black in normally pigmented individuals, appears light grey, but lacks melanin. Other normally pigmented areas of the body also appear light grey, or are colorless. The cornified tips of the toes are black. The gills are light orange. The internal organs are visible through the white venter.

Nussbaum (1976, Misc. Publ. Mus. Zool. Univ. Michigan. 149:1-94) discussed three partial albinos from a single creek in Benton Co., Oregon. These specimens were not considered albinistic because they had dark eyes. Our specimen appears to have dark eyes in normal light, but the eyes appear deep red under bright light. Nussbaum et al. (1983, Amphibians and Reptiles of the Pacific Northwest, University Press of Idaho, 332 pp.) show a photograph of a *D. ensatus* larva also from Benton Co., Oregon. It is called an albino in the caption, but is not described in the text. We are unaware of any other reports of albino *D. ensatus* (Dyrkacz 1981. SSAR Herpetol. Circ. 11:1-32; Hensley 1959. Publ. Mus., Mich. St. Univ. 1:133-159).

The salamander is being raised to a larger size in captivity. (Contribution number 14 of the Old Growth Wildlife Habitat Program, USDA Forest Service.)

Submitted by **LAWRENCE L. C. JONES** and **R. BRUCE BURY,** U.S. Fish and Wildlife Service, Denver Wildlife Research Center, 1300 Blue Spruce Drive, Fort Collins, Colorado 80524, U.S.A. ●

ENSATINA ESCHSCHOLTZII OREGONENSIS (Oregon ensatina). **REPRODUCTION.** Much of what is known about the reproductive biology of western plethodontid salamanders is based on preserved specimens or laboratory observations. Although the ensatina *(Ensatina eschscholtzii)* is the most widespread, and often most abundant, western plethodontid, only a few descriptions of egg masses in nature are available (review by Stebbins. 1954. Univ. Calif. Publ. Zool. 54:47-124; Norman and Norman. 1980. Bull. Chicago Herp. Soc. 15:99-100). Oviposition has only been observed twice, and both were laboratory records (Stebbins, 1954). Stebbins (1954) indicates that female ensatinas are capable of moving the egg mass after it has been deposited, and thus the locations where eggs have been found are not necessarily the sites where egg deposition occurred. Here, we describe the first observation of oviposition by *E. eschscholtzii* under natural conditions.

On 1 May 1984, a large female *E. eschscholtzii oregonensis* (109 mm TL, 63 mm SVL) was found in the central Cascade Mountains of Washington (5.6 km S, 1.5 km W of Packwood, Lewis County, T12N, R9E, Sec. 4, SW 1/4; elev. 700 m) in the act of egg deposition. Ten eggs had been laid in a gelatinous grape-like cluster as described by Stebbins (1954). The last egg protruded from her vent, but was still attached by a strand of jelly. No remaining eggs were visible in her abdomen. The salamander was observed for about 10 min, and remained motionless throughout this period in a twisted, prone position (Fig. 1). Her position was similar to that described and illustrated by Stebbins (1954, p. 93) for *E. e. picta-oregonensis* intergrades under laboratory conditions, but differed in several ways. She was lying on her left side, rather than her right, exposing the lower right portion of her abdomen. Because of this, her right front foot was stretched back, whereas her left front foot rested on the surface of the cavity. Her hind feet were spread widely apart, not pressed against the egg mass, and her tail was outstretched rather than curled. As was noted by Stebbins (1954), the gular region pulsated intermittently.

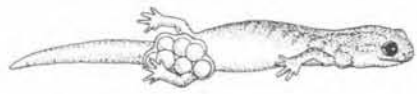

Figure 1. Position of female *Ensatina eschscholtzii oregonensis* during oviposition.

The salamander was found inside a downed red cedar *(Thuja plicata)* log, measuring 36 cm in diameter and 10 m in length. The log still retained its original shape, but the bark was gone and the sapwood had begun to decompose (= decay class 3; Maser et al. 1979. *In* Thomas. Wildlife habitats in managed forests: the Blue Mountains of Oregon and Washington. USDA For. Serv., Agric. Hndbk. No. 553, pp. 78-95). The ensatina was in a small cavity 8 cm beneath the surface of the log. The surrounding vegetation consisted of a dense stand of second growth coniferous forest resulting from a fire about 65 years ago. Dominant species were Douglas-fir *(Pseudotsuga menziesii),* western hemlock *(Tsuga heterophylla),* and red cedar, with little understory. It was raining lightly at the time of capture (1527 hr) and the air temperature was 5° C. The log was located on a fairly steep (41%) slope, facing northeast (44°). *E. eschscholtzii* was the only species of salamander found during a four person-hour search of the stand. Ten individuals were collected, including five adult males, four adult females, and one juvenile.

Two eggs measuring 6.2 mm in diameter were collected as vouchers and deposited in the Museum of Vertebrate Zoology at the University of California, Berkeley (MVZ 190828).

We thank Barbara Schrader for assistance in the field, and R. Bruce Bury for reviewing an early draft of the manuscript. This note is contribution No. 24 of the Old-growth Forest Wildlife Habitats Program, USDA Forest Service.

CROCODILIA

CROCODYLUS ACUTUS (American crocodile). **AGGRESSIVE BEHAVIOR.** During a night survey in the dam of Pueblo Viejo, 30 km west of Maracaibo Lake, State of Zulia, Venezuela, on 13 June 1984, we tried to catch by hand a juvenile American crocodile *(Crocodylus acutus).* The first attempt was unsuccessful, but we observed that this animal was gripping in its jaws a hatchling of *C. acutus.* The disturbance apparently caused the juvenile to release the hatchling, which showed some injuries on the neck and lower jaw and died a few minutes later. After three further attempts we were able to capture the juvenile, which was 628 mm total length (324 mm

snout-vent length) and weighed 580 g. The hatchling was 267 mm total length (130 mm snout-vent length) and weighed 40 g. Both animals, especially the hatchling, seemed to be very lean. We had the same impression with five other hatchlings of *C. acutus* and two juveniles of *Caiman crocodilus* that were caught in the same dam. We suspect that this aggressive behavior of the juvenile (probably a two year old) may have been cannibalism. Cannibalism has been reported for many species of crocodilians, but in most instances has been reported for adults against juveniles or hatchlings (Staton and Dixon 1975. Mem. Soc. Cienc. Nat. La Salle 101(35):237-265; Medem 1981. Los Crocodylia de Sur América Vol. 1. Los Crocodylia de Colombia. Ed. Carrera, Bogota. pp. 140 and 175).

This behavior of *C. acutus* might be considered as exceptional and provoked by the scarcity of food in the dam, the borders of which had lost their marginal aquatic plants because of a severe drought in the area. It could also have been aggravated by the ecological disturbance created by the introduction of a fish, *Cichla ocellaris* (Pisces:Cichlidae), in the reservoir.

PALEOSUCHUS PALPEBROSUS (Dwarf Caiman). **MIGRATION.** From 1976 to the present the authors have been accumulating field data for evidence of terrestrial migrations in the crocodilian *Paleosuchus palpebrosus.* Previous references regarding aquatic or terrestrial, and passive or active migrations for other alligatorid genera in South America were summarized by Medem (1981, 1983. Los Crocodylia de Sur América, Vols. I-II, Colciencias, Bogotá, Colombia).

Details of our six records in the Guayana region of Venezuela are as follows: (1) Guri Airstrip, near the Río Tocomita, Estado Bolívar (07°46'N-63°06'W); a juvenile found on the airstrip in 1976, with a 220 mm snout-vent length (SVL). (2) Puerto Ordaz, Estado Bolívar (08°18'N-62°49'W); a juvenile found in a partially constructed drainage ditch on the job-site of an aluminum factory, adjacent to the Orinoco River, on 11 July 1976, with a 310 mm SVL. (3) El Manteco, Estado Bolívar (07°21'N-62°32'W); a juvenile found on a road beside the airstrip in 1978, with a 155 mm SVL. (4) Hato El Diamante, 16 km SE of El Manteco, Estado Bolívar (07°15'N-62°27'W); a male found on a savanna track on 15 July 1980, with a 595 mm SVL. (5) Gavilán, 40 km SSE of Puerto Ayacucho, Territorio Federal Amazonas (05°34'N-63°22'W); a juvenile (EBRG 1795) found in a small puddle on a forest road in November 1980, with a 340 mm SVL. (6) Granja Santa Bárbara, 4 km E of San Félix, Estado Bolívar (08°23'N-62°37'W); a male found in the swimming pool of a farmhouse on 3 February 1981, with a 560 mm SVL.

The recorded sites were as far as 4 km to the nearest evident bodies of water and the encounters with crocodilians were made both during the day and at night. The preferred habitats of *P. palpebrosus* in Venezuela are rivers and "morichales" (palm swamps), but it is probable that they also occupy seasonal lagoons flooded by large rivers, even though we have never found this species in such circumstances.

Terrestrial migrations were observed in both tropical seasons (dry and rainy), suggesting that such behavior in these crocodilians occurs throughout the year. This type of migration seems not to be related to age, since both young and adult crocodilians were recorded migrating. The relationships of the terrestrial migration with ecological factors remain unknown at the present time in *P. palpebrosus,* but they could be partially associated with occasional searching for food, as evidenced in the alligatorid *Caiman crocodilus* (Gorzula 1978. Oecologia(Berl.) 35:21-34) from the northern savannas of the Venezuelan Guayana.

SAURIA

CNEMIDOPHORUS SEXLINEATUS VIRIDIS (Prairie-lined Racerunner). **ARBOREALITY.** On 17 May 1984 we witnessed an unusual escape behavior of a female prairie-lined racerunner at a sandy open area bordered by a woodlot 5.5 miles N of Lake Texoma on U.S. Hwy 377, Marshall county, Oklahoma. At 1830 CDT we dug the lizard out of its overnight burrow in the sandy area and chased it approximately 12 m to the edge of the woodlot. It ran another 3 m to the base of a post oak tree (diam. approx. 15 cm). As BCH approached, the lizard climbed the trunk of the tree using a wriggling motion similar to that of a skink. It moved from the south to the north side of the tree as it climbed and reached a height of 2 m before it was captured.

This behavior is unusual because this species is strictly terrestrial and typically escapes danger by dashing into a burrow or a clump of vegetation (Fitch 1958. Univ. Ks. Publ. Mus. Nat. Hist. 11:11-62; Hardy 1962. Univ. Ks. Sci. Bull. 43:1-73) although it has been reported to dive into water when threatened (Stille 1947. Copeia 1947:143). Young racerunners commonly climb to heights of nearly 1 m in bushes to forage (MAP, pers. obs.) but this type of climbing has never been noted as an escape behavior. Tree-climbing probably represents an escape method that racerunners use when other means of escape are unavailable.

The lizard (SVL 72 mm, total 170 mm) is presently housed at the Animal Behavior Lab, University of Oklahoma.

Submitted by **MARK A. PAULISSEN** and **BRET C. HARVEY,** Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, U.S.A. ●

EUMECES CALLICEPHALUS (Mountain Skink). **REPRODUCTION.** The mountain skink, *Eumeces callicephalus,* barely ranges into the United States. In Arizona, it is known from the Pajarito, Baboquivari, Santa Rita and Huachuca Mountains (Stebbins. 1966. A field guide to Western reptiles and amphibians; Smith and Brodie. 1982. Reptiles of North America). Little is known concerning reproduction in this species. However, it is reported to be oviparous (Fitch. 1970. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 52.).

On 2 June 1983, an adult female (15 cm total length) was collected by Pete Mayne at Pena Blanca Canyon, Santa Cruz County, Arizona at 1649 hr. The specimen was kept in a 19 l aquarium with leaf litter as a substrate. After several weeks it was apparent that the specimen was gravid, as indicated by increased girth. At this time it was placed in a plastic shoe box with damp mulch and flat rocks. The box was checked daily, and on 13 August, one neonate was found in the box. On 14 August, a second, dead neonate was seen protruding from the female's cloaca. This specimen was born tail-first.

The neonates were vividly colored but similar in pattern to the adult. They measured approximately 1.5 cm total length. The first neonate died after a few days. Both are preserved in the collection of Arizona State University (ASU 22808, 09).

Additional females will have to be collected to determine if this is an isolated occurrence or if all northern populations of *E. callicephalus* are ovoviviparous.

Submitted by **TOM TAYLOR,** 1433 West Huntington Drive, Tempe, Arizona 85282, U.S.A. ●

SCINCELLA LATERALIS (Ground Skink). **PREDATION.** On 9 April and 23 April 1983 the senior author (MK) collected 16 and 19 eastern meadowlarks *(Sturnella magna),* respectively, in tallgrass prairie habitat in Pawnee County, Oklahoma. All birds were collected between 0930 and 1030 hr. Esophageal and gizzard contents were removed and preserved in 70% isopropyl alcohol. Food samples from one adult male and two adult females (8.6% of the birds sampled) contained lizard remains; two contained unidentifiable skink tails while the third sample contained one *Scincella lateralis* (SVL = ca 46 mm).

Previous meadowlark food habit studies have not shown lizards to be a component of meadowlark diets (Beal 1926. Some common birds useful to the farmer. U.S.D.A. Farmer's Bull. 630 (rev.). 27 pp.; Beal, McAtee and Kalbach. 1927. Common birds of southeastern United States in relation to agriculture. U.S.D.A. Farmer's Bull. 755. 39 pp.; Bent 1958. Life history of blackbirds, tanagers, and orioles. U.S. Nat. Mus. Bull. 211:67-70; Martin, Zim and Nelson. 1951. American wildlife and plants: A guide to wildlife food habits. Dover Press, New York, pp. 167-168). Our findings are not surprising in light of the fact that Terres (1956. Auk 73:289-290) reported a meadowlark feeding on a road-killed tufted titmouse *(Parus bicolor)* and Redelfs (pers. comm.) reported that a meadowlark killed and ate a house sparrow *(Passer domesticus).* Since *S. lateralis* is a relatively small

lizard we feel that meadowlarks may prey heavily on small individuals of larger species such as sub-adult and hatchlings if available. Meadowlarks should be considered potential lizard predators in future ecological studies.

Submitted by **MICHAEL R. KEMMERER,** Oklahoma Cooperative Wildlife Research Unit, Oklahoma State University and **GEORGE R. CLINE,** Department of Zoology, Oklahoma State University, Stillwater, Oklahoma 74078, U.S.A. ●

UROSAURUS ORNATUS (Tree Lizard) **REPRODUCTION.** Numerous reports on the clutch size of tree lizards have revealed considerable variation both within and between populations. The maximum clutch size previously reported appears to be 16 from a population in Animas, Hidalgo, Co., New Mexico (Michel 1976. Southwest. Nat. 21:281-299), whereas most populations tend to have maximum clutch sizes of 12 or less (van Loben Sels 1976. MS Thesis. Arizona State University). We report here on a female which was carrying 17 oviductal eggs.

The female was collected from the eastern slope of the Organ Mountains at Aguirre Springs, 25 air km east of Las Cruces, Dona Ana Co., New Mexico on 20 June 1984 and kept isolated from males in an indoor tank. When killed and dissected on 19 July 1984, nine eggs and nine corpora lutea were found on the right side; eight of each on the left side. Mean egg wet weight was approximately 155 mg. The intact female weighed 7.6 g. Eggs contained well-developed embryos (Hubert and Dufaure stage 25-26) and complete egg shell membranes. Thus, this species represents an egg retainer as defined by Shine (1983. Herpetologica 39:1-8).

Van Loben Sels (1976, MS Thesis. Arizona State University) suggested that clutch size in this species is lower in arid regions than in mesic riparian areas. The largest reported clutch sizes to date, however, have been recorded from saxicolous populations in arid regions of southern New Mexico. This suggests that the shorter reproductive activity season in New Mexico, when compared with that of Arizona and central Texas, may result in larger clutch sizes which compensate for the reduced number of clutches being produced in a year (Michel 1976. Southwest. Nat. 21:281-299).

Thanks are due Ms. Rita Lawlor for help in collecting the specimen.

Submitted by **NAIDA ZUKER,** Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003-0032, U.S.A., and **LOUIS J. GUILLETTE JR.,** Department of Biological Sciences, Wichita State University, Wichita, Kansas 67208, U.S.A. ●

SERPENTES

BOTHROPS ASPER (Terciopelo). **CAUDAL LURING.** Two gravid *Bothrops asper* were collected in early June 1984 in Cartago province, Costa Rica. Broods of 34 (with two stillborn) and 37 were recorded on 14 July and 18 August 1984. Neonate sexing was accomplished by noting the presence (male) or absence (female) of yellow tail coloration and later verified by probing in some individuals. In a total of 69 living offspring, there were 30 males and 39 females. Reproductive data are given elsewhere (Tryon. 1985. Life History Notes. Herp. Review 16(1)).

Neonates were housed in various sized enclosures with newspaper substrate. The number of specimens in each varied but always consisted of two or more. Newborn mice were offered at weekly intervals once initial sheddings were completed. These were eventually accepted by approximately fifty percent of the snakes over a several month period. Between rodent feedings, eight instances of cannibalism occurred at night but were never observed.

Caudal luring was noted on several occasions in male and female snakes from both broods. These snakes assumed a tight coil with the distal 5-10 mm of the tail exposed from between coils and close to the head (behind or to one side). In each instance, the exposed tail tip was undulated gradually from side to side. The rate of motion was so slow that luring activity would probably not have been noted had changed tail position been overlooked in an otherwise motionless snake. Luring activity did not seem to be associated with the presence or absence of food items and occurred at various times throughout the day.

Burger and Smith (1950. Science 112:431-433) reported the occurence of sexual dimorphism in tail coloration of neonate *B. asper* from certain locales. They noted that the young snakes accepted a diet comprised of small frogs and several varieties of snakes (including littermates), and speculated that this variation in diet might be associated with the failure to develop brightly colored tail tips in both sexes. During their observations, the snakes' tails were often held up to a degree but actual luring behavior was not seen.

It has been generally accepted that snakes which employ caudal luring are those with a conspicuously colored or patterned tail tip (see Neill. 1960. Quart. J. Florida Acad. Sci. 23:173-200, for a review). It seems reasonable to assume, however, that in a species such as *B. asper,* luring behavior *per se* would not be restricted according to sex or to a sexually dimorphic caudal coloration. Investigations into feeding strategies and behavior, and food preferences of neonatal *B. asper* under natural conditions or controlled captive conditions may be necessary before the relative effectiveness of luring between sexes can be demonstrated, and a plausible explanation for sexually dimorphic caudal coloration can be presented.

For various courtesies I thank R. A. Nichols and J. Whitehead.

Submitted by **BERN W. TRYON,** Department of Herpetology, Knoxville Zoological Park, P. O. Box 6040, Knoxville, Tennessee 37914, U.S.A. ●

BOTHROPS ASPER (Terciopelo). **REPRODUCTION.** *Bothrops asper* is a large (exceeding 240 cm), prolific pit viper found from southern Veracruz south through Central America to northern Colombia (Wilson and Meyer. 1982. The snakes of Honduras. Milwaukee Pub. Mus. Publ. Biol. Geol. 6:1-159). Broods of up to 71 have been reported (March. 1928. Bull. Antiv. Inst. Amer. 1(4):92-97) from females of maximum size. Reproductive records are available from several localities throughout the range, but few have been taken from Costa Rican specimens (see Fitch. 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1-247, for a review).

Two gravid females (KSP-CR-37, 38; total length approximately 1.5 m) were taken in early June 1984 at an elevation of 600 m at Fincada Celolosa, Pavones de Turrialba, Cartago province, Costa Rica. Birth occurred on 14 July (CR-37) and 18 August 1984 (CR-38). Brood sizes were 34 (including two stillborn) and 37 respectively. Sexing was accomplished by the presence (male) or absence (female) of yellow tail coloration (see Burger and Smith. 1950. Science 112:431-433) and later verified by probing in some specimens.

Brood one was comprised of 10 males and 22 females, and brood two of 20 males and 17 females. Measurements of brood two were as follows: males, TL 305-327 mm ($\bar{X}$=314.2), weight 8.1-9.7 g ($\bar{X}$=9.3 g); females TL 300-325 mm ($\bar{X}$=309.4) and weight 8.1-9.7 g ($\bar{X}$=9.1). Grand means (N = 37) were TL 312.0 mm and weight 9.2 g. Shedding occurred 8-12 days after birth in both broods.

For various courtesies I thank J. A. Campbell, R. Hudson and M. R. Hernandez. Appreciation is extended to G. C. Mora of the Departamento de Vida Silvestre, de la Dirreccion General Forestal, San Jose, Costa Rica, for granting permits. Some specimens have been placed in the vertebrate collection of the University of Texas at Arlington.

Submitted by **BERN W. TRYON,** Department of Herpetology, Knoxville Zoological Park, P.O. Box 6040, Knoxville, Tennessee 37914, U.S.A. ●

CROTALUS HORRIDUS (Timber Rattlesnake). **COLORATION;** On 1 May 1983 an amelanistic partial albino *Crotalus horridus* was collected 7 miles north of Bogata, Texas near Cuthand Creek in Red River County by Fred Wissinger. The specimen, a female, was ca. 450 mm total length when captured and was probably in its second or third year of life.

The specimen is completely lacking in melanin and has a ground color that is creamy white with a pinkish-yellow tinge. The body pattern consists of a series of pale orange blotches which are fused dorsally to form a continuous pattern at the anterior portion of the body. There is also a series of unconnected lateral blotches located anteriorly. The dorsal blotches become progressively narrower and eventually fuse with the lateral markings to form chevronlike crossbands that are connected mid-dorsally by a pale orange stripe. There is a considerable amount of yellow pigment suffused with the orange posteriorly. The tail is solid white and patternless. The head is pale orange to faint pink with an orange postocular stripe and the iris is pale pink with a red pupil.

Color anomalies in *C. horridus* from northern populations have been documented.

Hensley (1959, Pub. Mus. Mich. State Univ., Vol. 1, No. 4) reports albinistic specimens from Massachusetts, New York, Pennsylvania and North Carolina. In a review of albinism, Dyrkacz (1981, SSAR Herp. Circular No. 11) provided additional accounts of aberrant *C. horridus* from Iowa and Pennsylvania, however, both of these specimens possess black tails and cannot be considered amelanistic. Until this time, there have been no reports of amelanism in *C. horridus* from a southern population which exhibits the pattern characteristics of the formerly recognized Canebrake *(atricaudatus)* morph. The previous southernmost locality was given as Yancey County, North Carolina and the specimen was simply described as being xanthic with a faint pattern (Hensley, op. cit.).

Figure 1. Sub-adult amelanistic partial albino *Crotalus horridus* collected in Red River County, Texas.

The specimen has been maintained in the reptile collection at the Fort Worth Zoological Park since its capture and at the time of this writing (November 1984) is 1115 mm total length. Upon death, the specimen will be deposited in the Vertebrate Collection of the University of Texas at Arlington.

Submitted by **RICHARD HUDSON,** Department of Herpetology, Fort Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, Texas 76110, and **GARY CARL,** 4312 Merida, Fort Worth, Texas 76115, U.S.A. ●

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **COLORATION.** On 2 July 1984, an aberrantly patterned prairie rattlesnake *(Crotalus viridis viridis)* was collected by SLR approximately 5 miles S of Shawmut (NE1/4, section 8, T6N, R18E) Wheatland County, Montana. The male specimen has a snout-vent length of 79 cm, a tail length of 6 cm, and a mass of 230 g. The usual (brown-bordered-by-white) middorsal and lateral blotches are absent. The dorsum is light brown, apparently a normal ground color. Small black spots are scattered anteriorly on the middorsum. Rows of similar black spots are found on either side of the body at the junctures of the ventral and dorsal scales. The usual head coloration is absent, being a uniform light brown color with a subtle diffusion of black pigment on top. The iris of the left eye is darkened to the point that the pupil is difficult to discern. Most distinctive of all aberrant features is an irregularly shaped black dorsal blotch approximately 10 cm in length centered directly over the vent. This blotch is cut in the middle by two white triangles (one on either side). These triangles appear to be unpigmented skin. The venter is a uniform cream except on the tail where there exist several unpigmented patches similar to those described above. Head scalation conforms to the normal range of variation with one exception: the scales between the supraoculars and the top of the rostral failed to form. Instead, there exists a keratinized patch of skin. The tongue is pink, grading to white at the tips.

The snake described here does not conform to the more commonly described types of pattern and color aberration (e.g., stripes, albinos, melanos, patternless). It is similar, however, to three prairie rattlesnakes described by Gloyd (1958. Chicago Acad. Sci. 10(12):185-195. CA13357, CA6165, CA11058).

Submitted by **JOSEPH B. SLOWINSKI,** Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124 and **STANLEY L. RASMUSSEN,** 950 Lafayette, Apt. 303, Denver, Colorado 80128, U.S.A. ●

LEPTODEIRA ANNULATA ASHMEADI (Trinidad Garden Snake). **EGGS.** Here we report the presence of *L. annulata* eggs in the nests of leaf-cutter ants *(Acromyrmex octospinosus)* in the area around the Simla Research Station, Arima Valley, Trinidad, W.I. The central fungus chamber of a small nest (approximately 25 x 40 cm) from a cocoa plantation above Simla (elevation approximately 250 m), excavated 25 April 1983, yielded three elongate (33 x 10 mm) eggs of *L. annulata.* One egg, dissected and fixed immediately contained a 46 mm long embryo. The remaining two, placed in the fungus garden of a captive leaf-cutter ant colony *(Atta cephalotes)* and maintained at 25° C, were dissected and fixed on 10 June 1983. One of these embryos measured 163 mm in length. The central fungus chamber of another *Acromyrmex* nest situated at the bottom of the Simla road (elevation 200 m) excavated 4 May 1983 contained three elongate eggs. Two were fixed in alcohol immediately; one was ruptured and the other measured 35.5 x 10.1 mm. The correspondence in size between these and the *L. annulata* eggs (above) suggests that they are the same species although the embryos are not sufficiently developed for specific diagnosis. In both nests, the eggs were buried deep in the living fungus garden.

Emsley (1977, Md. Herp. Soc. Bull. pp. 201-304.) reports that the eggs of *L. annulata* "are laid between June and November in forest floor litter or other decomposing vegetation about two months after mating," but Emsley (pers. comm.) has no record of the source of this information and our findings of two clutches from *Acromyrmex* nests may cast doubt on this claim.

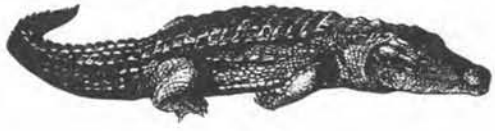
We are grateful to Mr. A. F. Stimson for identifying the snakes.

All the specimens are deposited in the British Museum (Natural History): (Registration numbers BMNH 1983: 1135, 1136, 1137; BMNH 1983: 298). This work was supported by NERC Grant No. GR3/5016.

Submitted by **JOHN RILEY** and **JUDITH M. WINCH,** Department of Biological Sciences, University of Dundee, Dundee DD1 4HN, Scotland. ●

TRIPANURGOS COMPRESSUS (Trinidad Pseudofalse Coral Snake). **EGGS.** An excavation of a large nest of the leaf-cutter ant *Atta cephalotes* above the Simla Research Station (Arima Valley, Trinidad, W.I.) on 1 May 1983 yielded 12 eggs of the colubrid *Tripanurgos compressus.* Since the excavation was carried out by a bulldozer, neither the exact location of the eggs in the nest nor the total number of eggs present could be precisely determined.

There were two distinct size categories of oval eggs: six measured 27 x 15 mm and six were 29.5 x 15 mm. One of the larger eggs was preserved and the remaining five, placed in damp sawdust and incubated at room temperature (28° C), hatched from 6-8 May. Hatchlings were kept alive for two weeks before being killed and preserved. Their mean length was 289 mm. Hatchlings did not feed while maintained alive.



Four of the smaller eggs were damaged and two of these were preserved immediately, two were discarded and the remaining two intact eggs were incubated in the fungus chamber of a small captive colony of *Atta cephalotes* maintained at 25° C. They were dissected and the embryos preserved on 10 June 1983. These embryos were 177 and 118 mm long.

The two distinct size categories of eggs, destined to hatch at very different times, suggest that two or more females oviposited in the same nest. Snakes are well known for their considerable intraspecific variation in egg size and several factors are known to influence this, for example, the size of the mother and the amount of food available to the mother. Thus the discovery of two egg clutches of *T. compressus* in a single nest is significant inasmuch as it provides stronger evidence that this species seeks out ant nests as egg-laying sites.

T. compressus is a nocturnal, terrestrial, locally common snake in forested areas where it feeds on lizards and probably arthropods (Emsley 1977, Md. Herpet. Soc. Bull. 201-304) and this is the only record of its life history. The utilization of leaf-cutter ant nests for brood provision is well known in a number of snakes on the mainland of South America (see Vaz-Ferreira et al. 1970, Physis, B. Aires 29:431-459; Vaz-Ferreira et al. 1973, Trab. V Congr. latinoam. Zool., 1:232-244).

All the specimens are deposited in the British Museum (Natural History): Registration numbers BMNH 1983.292-296, 297, 299, 300-301; 1983.1138). This work was supported by NERC Grant No. GR3/5016.

TESTUDINES

CLEMMYS INSCULPTA (Wood Turtle). **PREDATION-MUTILATION.** A fifteen year mark-recapture study in northern Michigan revealed that 12.5% (42/337) of marked wood turtles *(Clemmys insculpta)* had mutilated or amputated limbs (amputation defined as loss of at least one-half of one limb). Most of these injuries were sustained after the specimens reached adult size (carapace length at least 160 mm). Direct observation and circumstantial evidence point to the raccoon *(Procyon lotor)* as the cause of most limb mutilation.

To test the hypothesis that limb loss would compromise a turtle's long-term survival, a statistical comparison was made of recapture rates (minimum 10 month interval) for specimens with intact limbs (n=250) versus those with at least one amputated limb (n=38). The recapture rate for injured turtles was significantly lower than for intact animals ($p<.04$; details on request). However, multiple recaptures of several limb-mutilated female turtles on nesting beaches indicates that some individuals can overcome any disadvantage posed by limb loss as long as sufficient mobility is retained.

A different form of injury noted in several specimens was extensive damage to the shell caused by rodent gnawing activity, possibly beaver *(Castor canadensis)* or porcupine *(Erethizon dorsatum)* judging from incisor grooves in the bone. It is clear that the rodents are interested in the bony shell, perhaps as a source of calcium, and not in the turtles' flesh, which is often rendered exposed and accessible. Such shell damage is not immediately life-threatening, but might make the turtle more vulnerable to future predation.

KINOSTERNON SUBRUBRUM STEINDACHNERI (Florida Mud Turtle). **PATHOLOGY.** The occurrence of cystic calculi has been reported in captive-raised tortoises and attributed to dietary calcium/vitamin D imbalances. Frye (1972. J. Amer. Vet. Med. Assoc. 161: 600-602) surgically removed a large magnesium urate calculus from a 40 year captive *Gopherus agassizii.* Wallach (1969. J. Amer. Vet. Med. Assoc. 155:1017-1034; 1971. J. Amer. Vet. Med. Assoc. 159:1632-1643) noted the occurrence of cystic calculi in a captive *Geochelone elephantopus* and captive lizards and noted that calculi vary in composition from 98% calcium phosphate to mixed assemblages. Marcus (1981. Veterinary Biology and Medicine of Captive Amphibians and Reptiles. Philadelphia, Lea and Febiger) felt the altered captive diet was a probable cause of calculus formation. Cystic calculi have apparently never been reported from either wild or aquatic turtles, nor previously noted as a cause of mortality.

On 4 April 1984 I collected a mature male *Kinosternon subrubrum steindachneri* in Lutz, Hillsborough County, Florida (carapace length 95 mm, body weight 190 gm) in a relatively shallow permanent body of water. The base of the tail was slightly swollen and the perianal skin somewhat hypertrophied and erythematous. The animal appeared healthy. It occasionally attempted to unsuccessfully expel a firm mass from the cloaca. On 15 April the animal died suddenly, appearing listless for only about one or two days prior to death. A radiograph obtained immediately postmortem demonstrated a round calcific mass with concentric lamellae apparently lodged in the cloaca. At necropsy, a round calcific calculus measuring 15 x 12 mm was found impacted in the cystic neck (mouth of the urinary bladder) at its entry into the cloaca. The calculus was adherent to the cloacal walls with a surrounding area of chronic inflammatory response with necrotic debris and destruction of a large portion of the penis and cloacal wall. No gross perforatioan of the cloacal wall or cystic neck was noted. There was mild enlargement of the distal colon, suggestive of a low-grade chronic partial obstruction, but evidently colonic contents had been able to bypass the adherent calculus. Massive distension of the urinary bladder was present, without evidence of cystitis or perforation, suggestive of a high-grade chronic partial obstruction. The kidneys were of normal appearance and size. The rest of the necropsy was unremarkable. A cross-section of the calculus revealed distinct peripheral, hard, yellowish-brown concentric lamellae, with a chalky white dry powder without lamellae in the center. Identification of the calculus components by polarization microscopy supplemented by X-ray diffraction and infrared spectroscopy revealed 100% carbonate apatite, a form of calcium phosphate. The cause of death of the animal was felt to be septicemia from the cloacal infection secondary to the impacted cystic calculus.

The specimen is deposited in my personal collection, AGJR 304. I wish to thank Robert McAuley of the Department of Pathology, Burbank Hospital, Fitchburg, and Edwin Prien of the Laboratory for Stone Research, Newton, for their assistance in these investigations.

TRIONYX TRIUNGUIS (Nile Softshell Turtle). **HABITAT.** Some members of the softshell turtle family Trionychidae are known to tolerate high levels of salinity. *Pelochelys bibrani* has been found in coastal waters over a wide area in the Indo-Australian Archipelago and Asia (De Rooij 1915. Reptiles of the Indo-Australian Archipelago. I., Lacertilia, Chelonia, Emydosauria. Leiden, 384 pp) and *Trionyx spiniferus emoryi* occurs in brackish inland water (238.0 meq/liter) in the United States (Seidel 1975. Copeia 1:124-128). *Trionyx triunguis* often enters salt water in the Mediterranean (Geldiay et al. 1982, *In* K. A. Bjorndal, ed., Biology and Conservation of Sea Turtles, Smithsonian Institution Press, Washington, D.C., pp. 425-434; Sella 1982, *In* ibid., pp. 417-423), and two specimens were recorded by Villiers (1958. Initiatious Africaines, 15. Dakar) from the sea near Dakar. These last appear to be the only records for the West Coast of Africa.

During a recent survey of sea turtles made in Angola, West Africa, in September and October, 1983, we encountered the Nile softshell turtle, *Trionyx triunguis,* in salt water, and found evidence that it nests on ocean beaches. In Luanda we identified a "sea turtle" being kept in a fountain after having been caught in the sea off Luanda. It was a Nile softshell. At Barra Do Bengo, north of Luanda, a local fisherman informed us that softshell turtles frequently nested on the beach, near the river mouth. At Cabo Ledo, a small settlement in Kissama Park, south of Luanda, over 40 km from any fresh water, beachside residents told us that "river turtles nest here on the beach." At Barra Do Dande, we found the fresh shell of a *Trionyx* which had been butchered and eaten after drowning in a gill net that had been set in the sea, off the river mouth.

Sea turtle fishermen in Baia Do Mussulo, a salt bay just south of Luanda and 70 km from the nearest fresh water source, told us that local people had recently captured a Nile softshell. They said that this was a kind of sea turtle, and that it was commonly found in the salt bay the year around. While making an aerial beach survey in the Province of Cabinda we found the tracks of a softshell that had come ashore 200 meters upstream from the mouth of the Rio Chiloango estuary, travelled over intervening ground to the beach, nested, and then gone on into the ocean surf. Throughout our interviews, wherever the subject of softshell turtles came up, the name most commonly used for them was *Mundo.*

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

TRETIOSCINCUS AGILIS. VENEZUELA: TERRITORIO FEDERAL AMAZONAS: Simarawoche. April 1973. W. Perez. Verified by A. Paolillo O. Museo de Biologia, Universidad Central de Venezuela (MBUCV 617). Mavaca, Rio Mavaca. 21 September 1981. J. Finkers. Verified by A. Paolillo O. (MBUCV 2059). First record for Venezuela. The prefrontal scales in the Venezuelan specimens are completely in contact, separating the frontonasal from the frontal, a condition not found in Brazilian (Vanzolini and Rebouças-Spieker. 1969. Pap. Avul. Zool. 22(13):123-144) and Suriname specimens (Hoogmoed. 1973. Notes on the Herpetofauna of Suriname. IV. The lizards and amphisbaenians of Suriname. Dr. W. Junk Publishers, The Hague. 419 p.). I consider that contact of prefrontals in Venezuelan specimens completes the variation found by Vanzolini and Rebouças-Spieker (op. cit.). Hoogmoed (op. cit.) suggested that the Oriximiná (Brazil) population is a distinct subspecies from that of Suriname, but the Venezuelan specimens exhibit common characteris-

tics with both the Suriname specimens (except for the 29 transverse dorsal scales against the 23-26 found in Suriname) and the Brazilian specimens in those details that Hoogmoed considered as indicative of subspecific differences. *Tretioscincus agilis* (Ruthven) occurs in Guyana (Ruthven. 1916. Oc. Pap. Mus. Zool. Univ. Michigan (22):1-4), Amazonia of Brazil (Vanzolini and Rebouças-Spieker, op. cit.; Vanzolini. 1972. Pap. Avul. Zool. 26(8):83-115), Suriname (Hoogmoed, op. cit.) and French Guiana (Hoogmoed and Lescure, 1975. Zool. Meded. 49(13):141-171). I express my acknowledgement to J. Finkers for sending me one of the specimens. P. E. Vanzolini and S. Ayala kindly read the manuscript and gave valuable suggestions.

UROCOTYLEDON WOLTERSTORFFI (Tornier). AFRICA: TANZANIA: Morogoro Region and District: Uluguru Mts, Bunduki, Uluguru Fly Fishing Association rest house. 7°01'S, 37°38'E. Ca. 1250 m. 20 December 1979. K. M. Howell. British Museum (Natural History) (BMNH 1980.288). According to Loveridge (1957. Bull. Mus. Comp. Zool. 117:189-190), the species was previously known only from "Tanga"; however three of the syntypes bear the locality "Hinterland von Tanga," and likely originated in the East Usambara Mts., possibly from Amani (55 km W of Tanga).

Wederkinch and others have collected specimens (Zoological Museum of Copenhagen, ZMUC R34492-501) in intermediate rain forest at Amani and Kwamkoro Forest Reserve (8 km SW Amani).

Van Eyslen (1962. Lacerta 20:30) reported on specimens purchased from a dealer and said to have come from Arusha (330 km northwest of Tanga). Two of these (TCWC 51832-3 Texas A & M University) were examined and identity confirmed, but their origin remains uncertain.

The specimen from Bunduki extends the range 250 km southwest of Tanga and Amani to the Uluguru Mts. and removes it from the list of species endemic to the Usambara Mts. (Wederkinch, *In* Rodgers and Homewood. 1982. Biol. J. Linn. Soc. 18:237-238).

We gratefully acknowledge the cooperation of Dr. J. M. Dixon, Texas A. & M. University, Dr. W. Peters, Zoologisches Museum Berlin, and Dr. P. Alberch, Museum of Comparative Zoology, Harvard, who kindly lent specimens for examination.

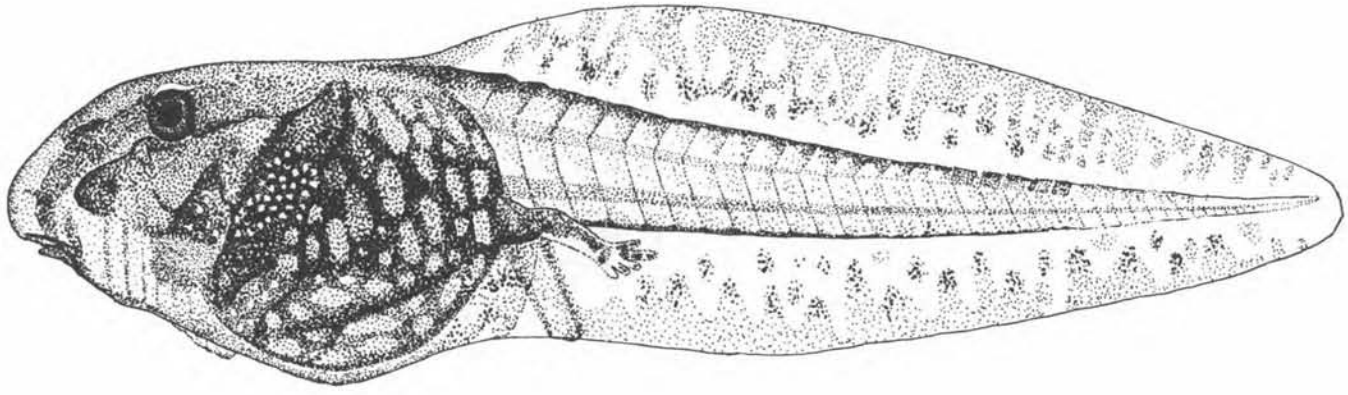
West Texas State University Museum of Nat. Hist. (WTSU 8896). New county record. Fills gap between previous county records (Dellinger and Black. 1938. Occas. Papers Univ. Arkansas Mus. 1, 47p.; Hurter and Strecker. 1909. Trans. Acad. Sci. St. Louis 18, 11-27; Dowling. 1957. Occas. Papers Univ. Arkansas Mus. 3, 51p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016, U.S.A. ●



TESTUDINES

CLEMMYS MUHLENBERGII (Bog Turtle). USA: MASSACHUSETTS: Berkshire Co: Sheffield. 26 May 1984 (2 females marked and released); 16 June 1984 (1 female marked and released); 16 September 1984 (1 juvenile marked and released. M. W. Klemens, P. G. Mirick, et al. Photographs deposited in the American Museum of Natural History. These turtles were collected in habitat ecologically similar to sites in northwestern Connecticut reported by Klemens and Warner (1983 *Herp. Review* 14(4):124-125).

We consider this the first documented record of this species in Massachusetts. Blanchard ("Richard" [*sic*] 1970 *Massachusetts Audubon* 55[1]:34-37) collected a specimen (subsequently lost, M. Flor, pers. comm.) at Pittsfield, Berkshire County, but we have no evidence confirming Blanchard's report of bog turtles in the Pittsfield area.

A grant to MWK from the Massachusetts Nature Conservancy supported field work, and the Massachusetts Division of Fisheries and Wildlife provided assistance.

Submitted by **MICHAEL W. KLEMENS,** Department of Herpetology, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024 and **PETER G. MIRICK,** Nongame Section, Massachusetts Division of Fisheries and Wildlife, Field Headquarters, Westboro, Massachusetts 01581, U.S.A. ●

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

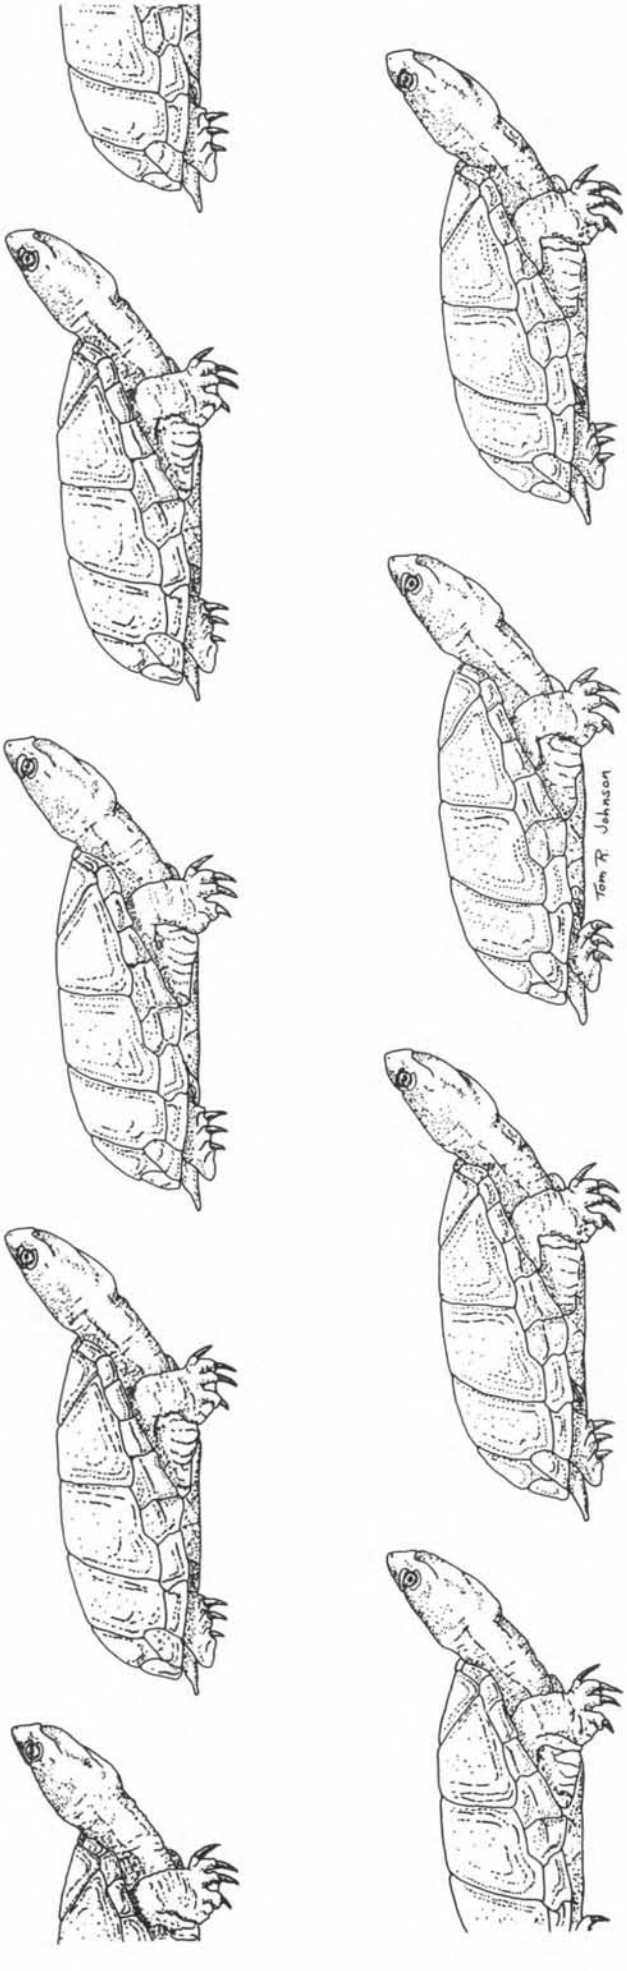
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), occasional issues of **Facsimile Reprints in Herpetology,** and **Recent Herpetological Literature.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1984

Student member	$17.00*
Regular member	$22.00*
Sustaining member	$35.00
Contributing member	$50.00
Institutional	$40.00

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).



*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1985 Grants-In-Herpetology Program. This Program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. All applicants (or their advisor or sponsor) must be a member of SSAR. Grant proposals will be considered in the following areas.

1. GRADUATE STUDENT HERPETOLOGICAL RESEARCH. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.
2. HERPETOLOGY-ORIENTED CONSERVATION. Proposals should address research on endangered or threatened species at the state, national or international levels, or address research on critical herpetological habitats. Proposals may be received from individuals only.
3. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.
4. HERPETOLOGICAL RESEARCH IN ZOOS. Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.
5. FIELD WORK (Auto mileage). Proposals may address any area of herpetological research and may be submitted by any member of SSAR. Funding will only be granted for expenses associated with auto travel for collecting (or observing) study animals.

Each proposal must include the following information: A) *Abstract*, B) *Background & Objectives* of the proposed project, in terms of its relevance to herpetology, C) *Methods* of carrying out the research or conducting the project, D) *Budget* for the project, which should not exceed $430 in each category, and E) *Curriculum Vitae* and *Letter of Support* (if applicable). The proposal must be typed double spaced and must *not* exceed five pages, excluding cover page, abstract, budget, curriculum vitae, and bibliography.

Successful applicants will be expected to submit to SSAR a written report of their research or project within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to *The Journal of Herpetology* or *Herpetological Review*.

Individuals submitting proposals must designate to which of the five areas their proposals applies. All proposals must be typewritten, submitted in duplicate, and postmarked no later than **12 APRIL 1985.** Failure to meet the deadline or follow the guidelines may result in rejection of the proposal. Submit proposals to:

Dr. James Bacon
Department of Herpetology
Zoological Society of San Diego
P.O. Box 551
San Diego, California 92112, U.S.A.

If you are employed by an organization which will match donations made to non-profit educational organizations, please notify your employer that you have made a donation to the Grants-In-Herpetology program.

●

1985 SSAR-HL MEETING

The March issue of *HR* will contain a detailed outline of the events scheduled for the Annual Meeting of the Herpetologists' League/Society for the Study of Amphibians and Reptiles, 4-9 August 1985, University of South Florida, Tampa, Florida, U.S.A. In addition to the HL Distinguished Speaker, concurrent paper sessions and poster sessions, and the annual auction, the following special events have been planned: A tour of Busch Gardens Zoological Park, a B-B-Q dinner at the Museum of Science and Industry in Tampa, and a trip to Archbold Biological Station. There will be a symposium presented by the Regional Herpetological Societies Committee, an updated slide show of "Herpetologists Past and Present," and an outstanding collection of the Florida herpetofauna available for viewing and photographing. The paper sessions will include numerous papers on Caribbean herptiles.

For further information contact meeting chairman:

Henry R. Mushinsky
Department of Biology
University of South Florida
Tampa, Florida 33620, U.S.A. ●

EXHIBITORS WANTED FOR 1985 JOINT SSAR-HL MEETING

The local committee for the 1985 SSAR-HL meeting is in the process of locating and contacting possible exhibitors for the meeting. Any individual or organization is welcome to display herpetologically-oriented material (except live animals). The following information may be useful in the design of exhibits or the recruitment of exhibitors.

Registrants: Biologists, college professors, zoo and museum personnel, state and federal wildlife officials, graduate students in biology and serious lay persons with interests in amphibians and reptiles.

Previous Exhibitors: Publishers, used book companies, biological supply companies, manufacturers of animal collecting and housing equipment, artists (with animal themes), tee-shirt sellers, and travel services.

Cost: $100 for each table (approx. 4x6 feet). Artists who sell materials created by themselves will be charged $100 or the equivalent in donated art or crafts; such persons are expected to be engaged actively in their work at the exhibit area.

Shipment and Care of Exhibits: Exhibits may be shipped (prepaid) in returnable containers to HL/SSAR, c/o H. R. Mushinsky, Department of Biology, University of South Florida, Tampa, Florida 33620 U.S.A. Exhibitors are encouraged to have their exhibits attended by an employee who can bring the materials with them. Exhibitors in attendance will be charged a much reduced registration fee; meals and social events will cost extra.

For exhibit application, or further information, contact:

Ruth Zantzinger
Box 1
Devault, Pennsylvania 19432, U.S.A.
(215) 933-0561 ●

ERRATUM

In the December 1983 issue of *HR* [14(4):99] T. R. Jones was listed as the author of the paper "Factors Affecting Home Range Size in the Iguanid Lizard *Sceloporus undulatus*," presented at the 1983 SSAR/HL meeting at the University of Utah. Although Mr. Jones presented the paper at the meeting, the project was conceived and conducted by, and the paper written by, Craig Levy in partial fulfillment of a master's degree at Arizona State University. ●

THANKS TO REVIEWERS

The Editor would like to acknowledge the following individuals who reviewed manuscripts for *HR* during the past year. Their service to the Society is greatly appreciated.

NEW *HR* MANAGING EDITOR

Herpetological Review is pleased to welcome John E. Simmons as the new Managing Editor, replacing George Pisani who resigned to assume his duties as President of the Society. John is Collections Manager of the Division of Herpetology, Museum of Natural History, University of Kansas in Lawrence. He has worked closely with the *HR* staff over the past several months and formally assumed his position on 1 January 1985. We appreciate John's willingness to assume this onerous task, pointing out that the quarterly rewards are more-than-adequate compensation for the unholy burden.

The Editor also expresses his gratitude to George Pisani, former Editor and Managing Editor of *HR*, for his assistance and counsel during the past two years. We wish him well during his year as President of the Society.

●

TREASURER URGES EARLY RENEWAL

Your Treasurer would like to remind everyone that a delay in renewing SSAR membership dues causes increased work for him and for the Publications Secretary as well as incurs additional expense to the Society. Delays in the delivery of publications can be as long as two to three months, for late renewals. At the recent SSAR Annual Meeting, the Board voted to assess $5.00 additional for renewals after the first issue of the Journal has been mailed. So please don't delay!

Our second class mailing privileges apply only to the U.S. Postal Zone. A typical issue of the Journal costs us 12¢ postage within the U.S. but 55¢ (minimum) for any non-U.S. address. That is the reason we impose a mail surcharge to all our non-U.S. colleagues.

HENRI C. SEIBERT ●

ABSTRACTS OF 1984 GRANTS-IN-HERPETOLOGY WINNERS

The SSAR Grants-In-Herpetology Committee receives, evaluates and prioritizes grant proposals from members in good standing in the SSAR. The Committee awards small grants (up to roughly $450) to the best proposals in five categories. In order to stimulate additional interest in these grants we are publishing the abstracts of the winning proposals for 1984.

GRADUATE STUDENT RESEARCH

1. Trip Lamb, Department of Zoology, University of Georgia. "An investigation of introgressive hybridization between the barking treefrog *(Hyla gratiosa)* and the green treefrog *(Hyla cinerea)* using mitochondrial DNA analysis."

Natural interspecific hybridization between *Hyla cinerea* and *H. gratiosa* has been observed and documented near Auburn, Alabama. Studies over 20 years have indicated that the basis of the hybridization has been the result of mismatings between male *H. cinerea* and female *H. gratiosa*.

While both morphometrics and electrophoresis have been important tools in the analysis of hybridization and introgression in the past, both have limitations. The use of mitochondrial DNA analysis is well suited to the evaluation of hybridization. The purpose of this study is to use mtDNA methods to delineate the direction and extent of hybridization between *H. cinerea* and *H. gratiosa* and to compare the results with those derived with conventional techniques.

2. Martha K. Pancak, Department of EPO Biology, University of Colorado. "Endocrine regulation of oocyte development in the Bidder's Organ, a remnant ovary in male toads."

Sequential hermaphroditism or sex reversal is a reproductive pattern exhibited by a number of vertebrates, for example, teleost fishes. Evolutionary and ecological models for the existence of sex reversal have been developed, but the regulatory mechanisms involved remain poorly known, particularly with respect to the role of hormones in this process. Male toads of the family Bufonidae provide excellent models for studying the hormonal interactions that occur during the transformation from male to female. Male toads possess a remnant ovary called the Bidder's organ which can become functional upon removal of the testes. The Bidder's organ consists of previtellogenic oocytes (premature egg cells) which yolk and mature only if the testes are removed. It is thought that the testes produce a factor which inhibits the Bidder's organ from growing, however, little is known about the inhibition of this remnant ovary. The following study comprises an investigation of the endocrinological basis for inhibition of oocyte development in the Bidder's organ. The project includes experiments which focus on pituitary involvement in sex reversal, inhibition of oocyte growth and maturation, as well as the interaction of gonadal steroids in regulating the process of vitellogenesis in bufonid toads. Results from the proposed experiments should provide useful information regarding mechanisms underlying sex reversal, as well as mechanisms of follicular arrest in the vertebrate ovary.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS

1. Joseph C. Mitchell, Department of Biology, University of Richmond. "Reptiles and Amphibians of southwestern Virginia: a biogeographical and ecological survey."

Although anecdotal notes exist on the composition of the herpetofauna of far southwestern Virginia, verification of the faunal elements has not been provided. Virtually no information exists on the natural history and ecology of these animals. A collection made in 1958 contained several state records and other important biogeographical records. This collection cannot be found and is presumed lost. The Virginia Herpetological Society proposes to conduct an intensive ten-day survey in this area to provide the much needed verification of the faunal elements and information on their natural history and ecological relationships. The latter information will be included in a forthcoming book on the herpetology of Virginia. If funded, the grant would help defray expenses of Virginia Herpetological Society members for travel, camping fees and food. Supplies, collecting equipment, and the expenses of the team leaders would be covered by another grant.

2. Yehudah L. Werner, Department of Zoology, Hebrew University of Jerusalem. "A gecko research facility."

The applicant's facility for holding and rearing geckos and other reptiles, in its 30th year, faces liquidation for fiscal reasons. The facility, on which most past research has been based, notably on vocalizations and physiological longevity, currently holds numerous *Ptyodactylus hasselquistii hasselquistii*, whose population is, within Israel, restricted to a small area. Support is sought for one year's feeding, caretaking and emergency repairs, in the hope of meanwhile obtaining a more substantial grant elsewhere.

HERPETOLOGICAL CONSERVATION

Robert E. Herrington, Department of Zoology, Washington State University. "The ecology, distribution, and habitat requirements of the Larch Mountain Salamander, Plethodon larselli."

The Larch Mountain salamander *(Plethodon larselli)*, is a rare, regional endemic species that occurs along a narrow 60 km section of the Columbia River gorge between the states of Washington and Oregon. This species is currently listed as threatened in both states; however, lack of information concerning this salamander's basic biology has resulted in its status being listed as "under review" by the U.S. Fish and Wildlife Service and the International Union for the Conservation of Nature and Natural Resources. The primary objectives of this investigation include the collection of quantitative data on the range, habitat requirements, and population ecology of this poorly understood species of salamander.

HERPETOLOGICAL RESEARCH IN ZOOS

Michael K. Stoskopf, National Aquarium in Baltimore. "Aminoglycoside kinetics in three families of Anura."

Amphibians are not immune to microbial invasion. The management and veterinary care of amphibians is complicated by a lack of information on antibiotic dosimetry. In particular, small amphibians present a challenge because in vivo antibiotic analyses require considerable blood volumes.

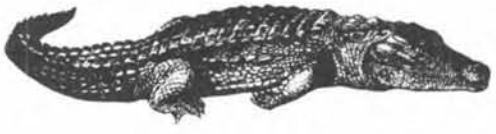
The medical department laboratories of the National Aquarium in Baltimore have combined the use of labelled aminoglycoside antibiotics, gentamicin and tobramicin, which reduces the necessary sample volume to 25 microliters for analysis.

The study will 1) determine the half life of each antibiotic in samples of species representing three anuran families; 2) evaluate impact of delivery route on serum levels and; 3) determine dosage regimens for therapeutic use.

FIELD WORK

1. Calvin A. Porter, Department of Zoology, Brigham Young University. "Chromosomal variation in the iguanid lizard *Sceloporus grammicus* in central Mexico."

The concept of stasipatric speciation, the genetic isolation of populations by chromosomal rearrangements, is being studied in the iguanid lizard, *Sceloporus grammicus*. There are five chromosomal races in the species, each fixed for a different chromosomal rearrangement.



This study proposes to sample and analyze the cytotypes of selected populations. The objectives will be to karyotype a large number of lizards in order to determine more accurately the distribution and frequency of chromosomal polymorphisms, and to determine the frequency of aneuploid gamete formation in individuals heterozygous for centric fusions and other polymorphisms.

The study may help determine if chromosomal rearrangements are causally related to speciation or if the two phenomena occur independently of each other.

2. Mac F. Given, Biological Sciences Group, University of Connecticut. "Social behavior and acoustic interactions of the carpenter frog, *Rana virgatipes*."

Prolonged breeding anurans generally have more complex social interactions than explosive breeders. I plan to observe the behavior of marked males and carry out several experiments on acoustic interactions of the prolonged breeding carpenter frog, *Rana virgatipes*, of the New Jersey Pinelands. No behavioral work has been done on this species, although its population ecology is well understood (Standaert, W.F. 1967. Ph.D. Thesis. Rutgers Univ.). Last summer, preliminary work established that the breeding season is prolonged, males are territorial and defend calling sites, and the male vocal repertoire consists of at least five distinct calls. This summer, I plan to determine: 1. the response of males to calls of different intensities; 2. whether calls of large vs. small individuals can be discriminated by males; 3. the response elicited by advertisement calls with either more or fewer notes per call than those given by the subject before the stimulus is presented (this call ranges from one to nine notes per call); and 4. whether body size is correlated with intensity, dominant frequency, and repetition rate of male calls, and whether these are related to male mating success. The results will be compared with the behavior of other prolonged breeding ranid frogs.

27th ANNUAL MEETING OF SSAR HELD AT THE UNIVERSITY OF OKLAHOMA

The 1984 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League and The American Society of Ichthyologists and Herpetologists in Norman, Oklahoma, during 28 July-4 August on the campus of the University of Oklahoma. Local Committee Chairman Victor H. Hutchison did a magnificent job of organizing the largest meeting of herpetologists and ichthyologists ever held. Excellent facilities were provided for the 963 members and guests attending from 20 countries. Paper sessions and exhibits were all held on campus and most attendees were housed nearby in comfortable dormitories.

SSAR Board of Directors Meeting

The annual meeting of the Board was held on Sunday, 29 July, under the chairmanship of President Carl Gans. All Board members, except Timothy Halliday, were present plus other officers, editors, committee chairs, and a number of visitors. The Board met for nine hours and discussed annual reports submitted by each Society officer, editor, committee chair, and coordinator plus a number of other topics.

In addition to the items announced at the business meeting on 30 July (see below), the Board also discussed the following topics: (1) a net increase in membership of 5.4% for 1983, (2) George Pisani's resignation as Managing Editor of *Herpetological Review* at the end of 1984, (3) John Simmons' appointment as Managing Editor of *Herpetological Review* effective 1 January 1985, (4) the possibility of holding the 1986 annual meeting at Old Dominion University, (5) a proposal to hold a symposium during the Tampa meeting on "Ecology and Behavior of West Indian Amphibians and Reptiles," (6) no presentation of Kennedy Student Paper Award for 1984, and (7) agreement by SSAR, HL, ASIH Liaison Committee to a policy addressing support of joint meetings.

Opening Ceremonies

The meeting began officially at 0900 hr on 30 July. On behalf of SSAR, HL and ASIH, Victor Hutchison welcomed members of the three organizations and introduced Dr. Kenneth Hoving, Dean of the Graduate College and Vice Provost for Research of The University of Oklahoma, who welcomed the societies on behalf of the University. Jay Savage introduced Marvalee Wake who presented the ASIH Presidential Address entitled "Caecilians and I—Our First Twenty Years." C. Richard Robins then introduced the ASIH Distinguished Fellow Lecture, "On the Importance of Marine Sanctuaries to Ichthyological Research," presented by John E. Randall. Ronald Brandon, President of Herpetologists' League, introduced the League's Distinguished Speaker, David Wake, who presented a special lecture entitled: "Species, Genes and Morphology—A Perspective on Evolution in Salamanders."

Symposia and Workshop

An NSF-sponsored symposium on "Predator-Prey Relationships in Lower Vertebrates" was organized by Martin E. Feder and George V. Lauder. The program consisted of 13 papers arranged in two sessions: I. Physiology and Morphology and II. Ecology and Behavior. The sessions were informative and very well attended.

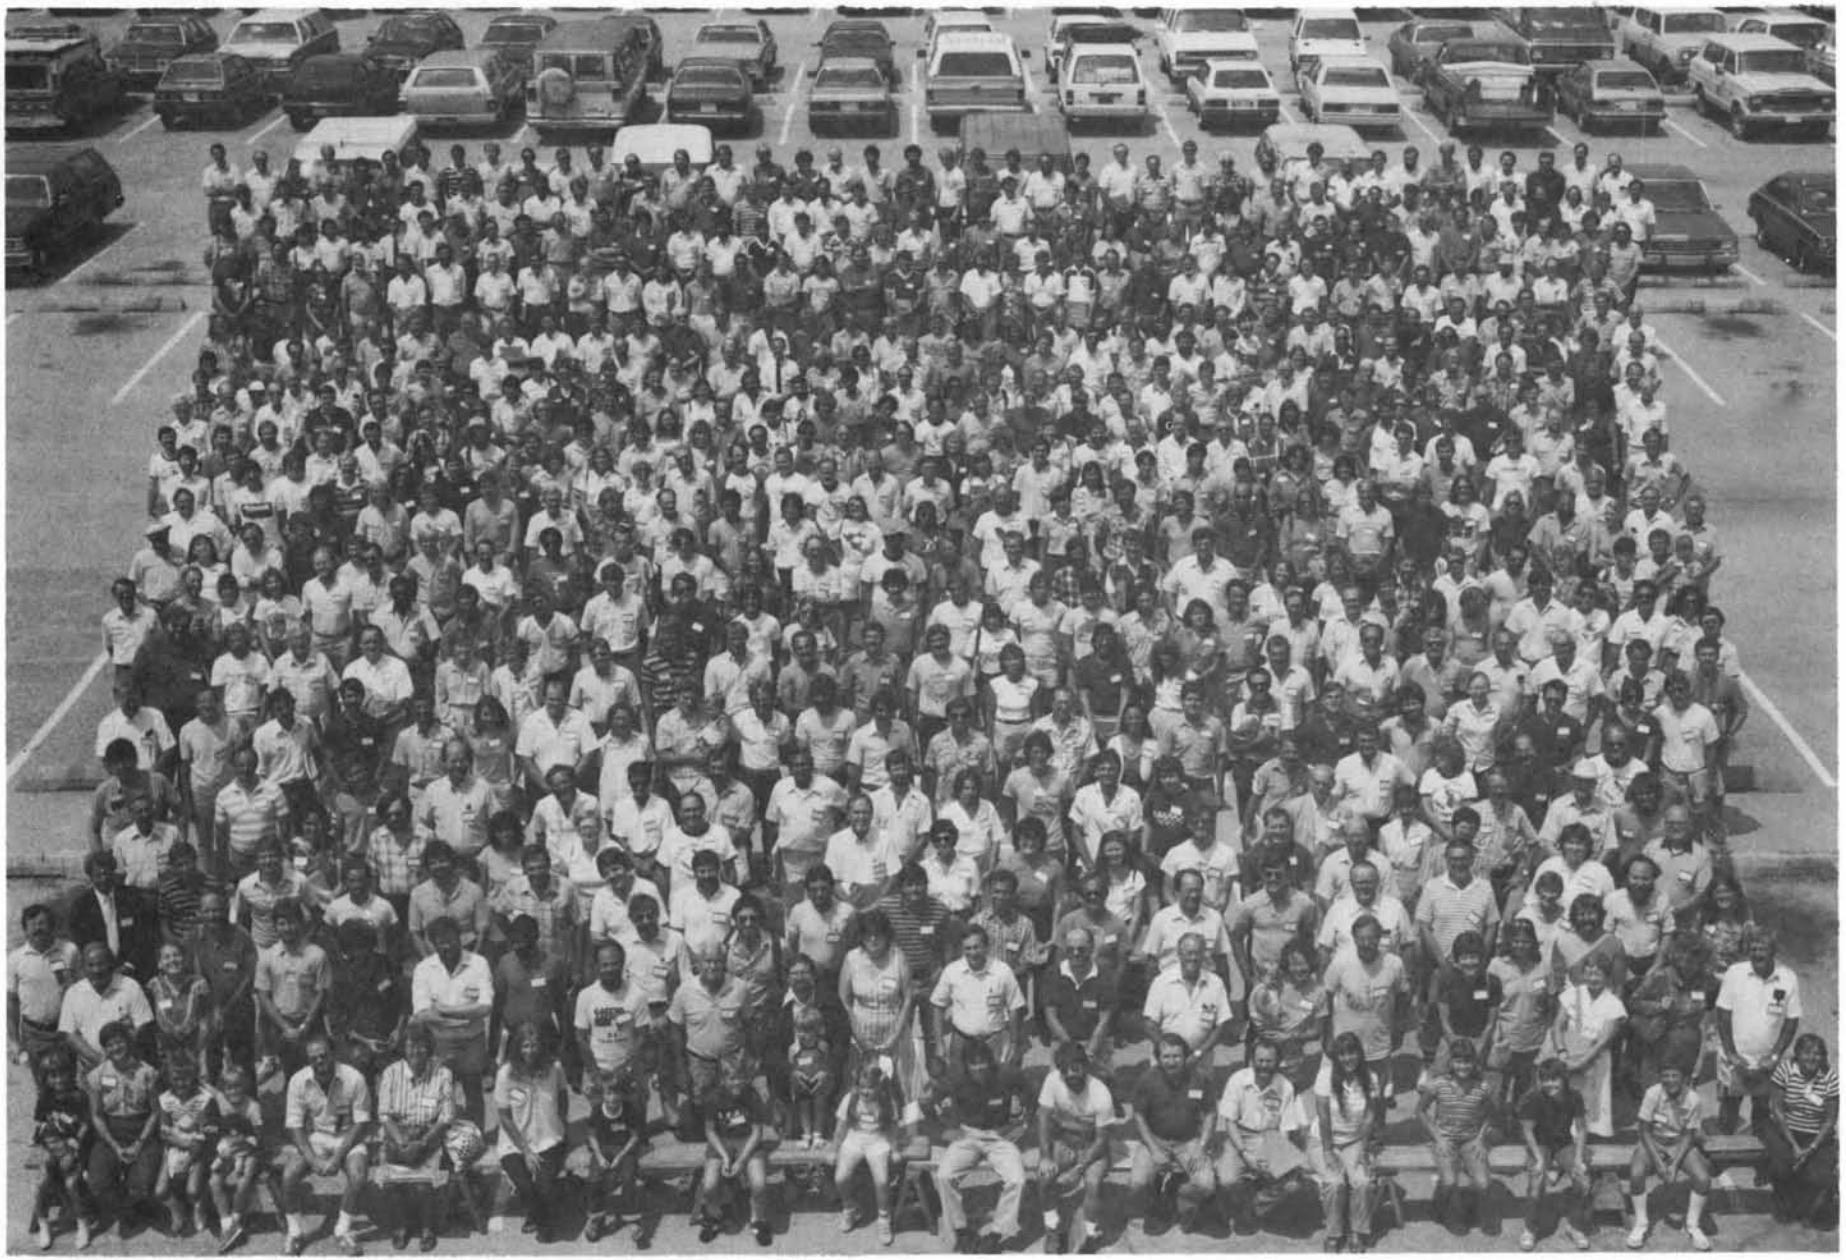
A workshop on "Larval Amphibian Biology" was organized by Richard J. Wassersug and sponsored by SSAR, HL, and ASIH. Over 50 people attended the productive and successful half-day session.

A symposium on "Biology of *Cnemidophorus*" was organized by John W. Wright. The program consisted of 25 papers plus a eulogy of T. Paul Maslin given by C. J. McCoy.

The SSAR Zoo Liaison Committee sponsored a symposium on "Management of Endangered Reptiles and Amphibians in Captivity." The program was organized and chaired by Peter J. Tolson.

The 8th Regional Herpetological Societies Conference was sponsored by the SSAR Regional Herpetological Society Liaison Committee. The program, "Monitoring Reptile and Amphibian Populations: An Important Role for Regional Herpetological Societies," was organized and chaired by Jeffrey H. Black.

Special Lectures on Chinese Herpetology



One of the highlights of the meeting, and an historic occasion for herpetology, was the presentation of lectures by the leading specialists from mainland China and from Taiwan, China. Over 200 people were in attendance for the special session arranged on behalf of SSAR by Kraig Adler (Cornell University). Professor Ermi Zhao (Chengdu Institute of Biology, Chengdu, Sichuan, China) presented "A brief review of the amphibians and reptiles of China." Professor Kuang Yang Lue (National Taiwan Normal University, Taipei, Taiwan, China) lectured on "The amphibians of Taiwan (Formosa), China."

Special Activities, Exhibits, Social Events, and Tours

Several excellent social events were held during the week-long meeting. They included a "start of meeting" social held Sunday evening, a barbecue and tour of the Oklahoma City Zoo on Monday, a picnic followed by an exhibit of Indian dancing on Wednesday, and a banquet on Thursday that featured roast bison. A number of family tours were also conducted, including a trip to Oklahoma City to visit the Cowboy Hall of Fame and Omniplex Science Center, and a guided tour to Anadarko to visit Indian City and the Museum of the Southwest Plains Indians.

One of the most popular events of the annual meeting, the SSAR auction, occurred on Wednesday night after the picnic with Joseph T. Collins continuing as auctioneer. The sale of herpetologically related art, publications, and other items raised money to help defray local meeting expenses.

SSAR sponsored the presentation of an updated version of "Herpetologists—Then and Now," a slide presentation set to music, which was prepared by David Dennis and Kraig Adler and first shown at the 1982 annual meeting in Raleigh, North Carolina. David

AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES HERPETOLOGISTS' LEAGUE
UNIVERSITY OF OKLAHOMA 28 JULY - 3 AUGUST 1984

Dennis and Eric Juterbock presented their magnificent multimedia program on "Amphibians of the Appalachians" and held another informative "Nature Photography Workshop." A large, excellent display of live amphibians and reptiles from Oklahoma and surrounding states was also available for viewing and photography.

Business Meeting

The annual business meeting of SSAR was called to order by President Carl Gans at 1630 hr on 30 July. President Gans welcomed SSAR members and visitors.

Secretary James Jacob announced that the Society is engaged in a library subscription campaign that offers substantial discounts on subscriptions and back issues of the *Journal of Herpetology* and *Herpetological Review*. He asked members to encourage their librarians to take advantage of this offer to purchase missing back issues or to initiate a new subscription. The Secretary announced two new policies approved by the Board of Directors at their annual meeting: (1) "By Title Only" papers will no longer be accepted at the annual meeting and (2) individuals who submit a paper and then fail to attend the meeting and do not arrange for a substitute presentor will not be allowed to submit a paper at the following annual meeting.

Treasurer Henri Seibert announced that (1) the Society is healthy financially, (2) there will be no increase in the cost of dues or subscriptions during 1985, (3) the Society is establishing endowment funds to help operate programs such as Grants-in-Herpetology and encouraged members to make contributions, (4) a $5 late charge has been instituted for membership renewals received after 20 January of each year, and (5) the Board of Directors approved a 1985 budget of $90,058.

Journal of Herpetology Editor Rodolfo Ruibal reported that (1) the number of manuscripts submitted during 1983 increased to 184; (2) he is projecting receipt of 210 manuscripts during 1984; (3) the *Journal* has been rejecting approximately 50% of the manuscripts submitted; (4) 100 pages per issue are published currently, but there will be an increase to 125 pages per issue during 1985; (5) this increase in published pages will result in a decrease in turnaround time for manuscripts from the current 12 month period; and (6) the Editorial Board of the *Journal* is being expanded and Associate Editors are being added in an effort to speed the handling of manuscripts.

Kraig Adler, Editor of *Facsimile Reprints in Herpetology* and *Contributions to Herpetology*, announced that (1) John Anderson's "Herpetology of Arabia" is in press and will be available by the end of the year, (2) Daudin's books "Histoire Naturelle des Quadrupedes Ovipares" and "Histoire Naturelle des Rainettes, de Grenouilles et des Crapauds" will be published in 1985, (3) Pritchard and Trebbau's "Turtles of Venezuela" will be available in the next few months as volume number 2 in the *Contributions* series, and (4) Gloyd and Conant's "Snakes of the *Agkistrodon* Complex" will be the next publication in this series.

Linda Maxson, Chair of the Grants-in-Herpetology Committee, announced the names of the winners in each category for 1984 and the titles of their proposals (see *HR* 15(3):62).

President Gans announced the following nominees for SSAR office in 1985:

President-elect:
Sherman Minton and Linda Trueb
Secretary:
James Jacob (unopposed)
Treasurer:
Henri Seibert (unopposed)
Board of Directors:
John Behler, E. D. Brodie,
Harold Dundee, and Carl Lieb

President Gans opened the floor for additional nominations and Neil Ford nominated John Simmons as a candidate for the Board of Directors (regional society position). No additional nominations were received and President Gans declared the nominations closed. The ballot for 1985 appeared in the September issue of *Herpetological Review*.

President Gans announced that SSAR has approximately $250,000 worth of books and reprints in storage and the Board of Directors has approved a program to offer substantial discounts on this inventory to members of the Society. Purchases will be limited to one copy or set per member. Details will be announced in *Herpetological Review*. Proceeds from this sale will be placed in an endowment for the Grants-in-Herpetology program.

In the absence of Resolutions Committee Chair George Gorman, President Gans offered the following resolutions:

1. *Whereas*, the Society members who retired from service last year have proven their devotion to SSAR by promoting its aims, *Be It Resolved*, that we thank: Ralph Axtell for serving as President, Kraig Adler for serving as Immediate Past President; Marvalee Wake and Max Nickerson for serving as Directors; and John Behler, Gary Ferguson, John Groves, Jim Jacob, Janice Perry, Jim Vial, and Dan Wilhoft for their service as committee chairpersons.

2. *Whereas*, Doug Taylor has served as SSAR Publications Secretary since 1977, and *Whereas*, he has devoted countless hours and infinite amounts of energy to his Society duties,
Be It Resolved, that the Society for the Study of Amphibians and Reptiles extends its thanks to him for his many years of devoted service and offers him a token of its appreciation.

The resolutions were approved by resounding applause and President Gans presented Taylor with a copy of a book specially prepared to commemorate his dedicated service to the Society. President Gans announced that the joint resolutions would be presented at the banquet on Thursday night.

President Gans called President-elect George Pisani to the stage, wished him luck during the coming year, and presented him with the official gavel which is held by the President during his term of office. Pisani thanked Gans and then asked Henry Mushinsky to present a summary of activities planned for the next annual meeting.

Henry Mushinsky, Local Committee Chair for the 1985 Annual Meeting in Tampa, Florida, gave a brief presentation on the arrangements for next year's meeting. He noted that (1) the meeting will be held during 4-9 August on the campus of the University of South Florida and that dormitories will be open on 3 August; (2) 600 beds have been reserved at a cost of $12.50 per person per day for double occupancy and $25 per day for single occupancy; (3) special off-campus housing rates have been arranged with the Holiday Inn across the street from the campus at $40 per day for single occupancy and $45 per day for double occupancy; (4) preregistration fees will not exceed $45 for regular members, $35 for students, $15 for partners, and $5 for children.

President-elect Pisani thanked Mushinsky for the presentation. There being no further business, the meeting was adjourned at 1707 hr.

Joint Resolutions

The following resolutions were presented at the Thursday banquet by George Gorman, Chairman of the joint SSAR, HL, ASIH Resolutions Committee. He also extended thanks, on behalf of the three societies, to Professor Ermi Zhao, Chengdu Institute of Biology, Chengdu, Sichuan, China; and Professor Kuang Yang Lue, National Taiwan Normal University, Taipei, Taiwan, China, for their enlightening talks on the herpetology of China.

1. *Whereas*, the ASIH, HL, and SSAR have a long heritage of mutually beneficial participation in their scientific programs and their business affairs by scientists of the U.S. Department of the Interior, Fish and Wildlife Service, who serve or have served as members of the Board of Governors, officers, editors, and chairmen and members of important committees, and who wish to conduct Society business and present papers based on U.S. Fish and Wildlife Service research programs, and *Whereas*, official participation of these scientists has been severely curtailed at recent meetings because of lack of administrative support, a requirement for extensive documentation and review, granting of authorization only after review at the level of Fish and Wildlife Service Director or Assistant Secretary of the Interior, and official policy memoranda by the Director of the Fish and Wildlife Service discouraging such participation as of lowest travel priority, and
Whereas, the U.S. Fish and Wildlife Service is the federal agency most responsible for and deeply involved with research and management of vertebrate populations in the United States, and
Whereas, communication with government scientists at meetings provides a means of input from the scientific community to federal research and management policies, and
Whereas, meetings of professional and scientific societies promote an interchange of ideas that increases the quality of research and stimulates new approaches to solving problems, thus promoting greater efficiency in federal programs, and
Whereas, exchanges at meetings often lead to vastly increased cooperation between the private and public sectors of the research community that, in turn, can result in the avoidance of repetition, competition, and redundancy of effort by different parts of the research community, and

Whereas, the curtailment of attendance of the U.S. Fish and Wildlife Service scientists at meetings of the professional societies will ultimately result in the impoverishment of the quality and quantity of research and management accomplished by the federal government,
Therefore Be It Resolved that the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles urge the Department of the Interior, U.S. Fish and Wildlife Service, to adopt a more enlightened view regarding scientific meetings and consequently assign a higher priority to attendance by the scientific staff.

2. *Whereas,* Alice G. C. Grandison, our esteemed herpetological colleague and Honorary Foreign Member of the American Society of Ichthyologists and Herpetologists, has recently retired from her curatorial duties at the British Museum (Natural History),
Now Therefore, the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles join in extending best wishes upon her retirement.

3. *Whereas,* the members in attendance at the annual meeting of the ASIH, SSAR and HL met on the beautiful and green campus of the University of Oklahoma; and
Whereas, due to the excessively high consumption of beer, necessitated by the 3.2% alcoholic content, the campus was made even greener as the meetings progressed;
Now Therefore, be it resolved that the ASIH, SSAR, and HL thank the State of Oklahoma for permitting students of cold blooded vertebrates to broaden their perspectives by gaining data on mammalian renal physiology and sociological information on the greening of America.

4. *Whereas,* 963 registrants from three societies invaded a quiet university town; and
Whereas, these 963 registrants received incredibly efficient and courteous service, including but not limited to: arrangements for transportation to and from the airport; adequate dormitory housing; belly dancing; beer; ample, edible, and inexpensive cafeteria food; beer; exhibits of live animals; a lively auction fueled by beer; a superbly printed program with sessions carefully planned; coffee and donuts; more beer,
Now Therefore, be it resolved that these 963 registrants representing the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles extend their thanks and appreciation to:

1. The University of Oklahoma, our host institution, and Dean Kenneth Hoving, Dean of the Graduate College and Vice Provost for Research, who opened our meetings;

2. The Oklahoma City Zoo and Director Lawrence Curtis for putting on a feast enjoyed by all;

3. The Norman Chamber of Commerce, The University of Oklahoma Foundation, the Oklahoma Herpetological Society, the Tulsa Zoo and the Zoology Department, Oklahoma State University—all of whom served as hosts;

WORKSHOP ON LARVAL AMPHIBIAN BIOLOGY From left to right: R. J. Wassersug, R. Inger, B. Shaffer, T. E. Hetherington.

4. The Local Committee comprised of the following subcommittees: (a) Program, Charles C. Carpenter, Chairperson; (b) Audio-Visual, Robert Richardson, Chairperson; (c) Signs and Graphics, Lynette Sievert, Chairperson; (d) Poster Sessions, Mark Paulissen, Chairperson; (e) Commercial Exhibits, Robert S. Rawding, Chairperson; (f) Live Exhibits, Stephen M. Secor, Chairperson; (g) Art Exhibit, Linda Trueb, Chairperson; (h) Family Tours and Child Care, Steve Kashuba, Chairperson; (i) Housing, David White and James H. Martin, Chairpersons; (j) Auction, Brian Paulson, Chairperson; (k) Social Functions, William Shelton, Chairperson; (l) Transportation, Wendal Porter, Chairperson; (m) T-Shirt Sales, Michael Lodes, Chairperson; (n) Registration-Information, Cindy Jolls, Chairperson; and (o) Zoo Barbecue and Open House, David Grow, Chairperson.

Whereas, Vic Hutchison chaired the largest gathering of Herpetologists and Ichthyologists in recorded history; and
Whereas, Vic Hutchison managed to continue to function throughout the meetings without once reaching his critical thermal maximum and without losing his righting response;
Now Therefore, be it resolved that all gathered at this banquet give Vic a standing ovation to thank him for the incredible organization at a most successful meeting.

Papers and Posters Presented:

A total of 337 papers and 74 posters were presented in 40 sessions during the five-day meeting. Papers and posters dealing with herpetology are presented below. Titles dealing with ichthyology appeared in *Copeia* 1984(4).

JOINT OPENING SESSION
CHAIRPERSON: VICTOR H. HUTCHISON

MARVALEE H. WAKE, University of California, Berkeley.
ASIH Presidential Address: **"Caecilians and I - Our First Twenty Years."**
JOHN E. RANDALL, Bishop Museum, Honolulu, Hawaii.
ASIH Distinguished Fellow Lecture: **"On the Importance of Marine Sanctuaries to Ichthyological Reseach."**
DAVID B. WAKE, University of California, Berkeley.
Herpetologists' League Distinguished Herpetologist Lecture: **"Species, Genes and Morphology - A Perspective on Evolution in Salamanders."**

CONTRIBUTED PAPER SESSIONS

(Papers and posters dealing strictly with ichthyological topics have been deleted. These titles appear in Copeia 1984(4).)

SYSTEMATICS I: AMPHIBIANS AND REPTILES
CHAIRPERSON: JAMES DIXON

DRYSDALE, T. A., University of Guelph.
Electrophoretic distinction of *Bombina variegata pachypus.*
WERMAN, S. D., University of Miami.
Biochemical systematics of neotropical pit vipers.
GUYER, C., University of Miami.
Phylogenetic relationships of anoline lizards: a reanalysis of osteological data.
JONES, T. R., Arizona State University.
An alternative hypothesis to explain the distribution of night lizards *(Xantusia)* based on plate tectonics.

POYNTON, J. C., University of Natal, South Africa.
Amphibian distribution in South Africa: some major features and research opportunities.
BAEZ, A. M., Universidad de Buenos Aires and Rice University.
Cretaceous and Early Tertiary pipid frogs from South America and their evolutionary significance.
IRISH, F. J., Harvard University.
Evolutionary implications of tooth replacement patterns in snakes.
LUKE, C., M. Hymen and H. Greene. University of California, Berkeley and Field Museum of Natural History.
Convergent evolution in sidewinding snakes.

SYSTEMATICS IV: AMPHIBIANS AND REPTILES
CHAIRPERSON: JOHN LYNCH

BUSACK, S. D., University of California, Berkeley.
Genetic differentiation in a Mediterranean herpetofauna: does paleogeography explain it all?
LOWCOCK, L. A., University of Guelph.
Genetic continuity in peripheral populations of salamanders of the *Ambystoma jeffersonianum* complex: a preliminary report.
ROMANO, M. A., D. B. Ralin, S. I. Guttman and J. H. Skillings, Miami University.
Parallel electromorph variation in the cryptic gray treefrog species *Hyla chrysocelis* and *Hyla versicolor*. Presented by Jack R. Layne.
MIYAMOTO, M. M., M. P. Hayes and M. R. Tennent, University of Miami.
Biochemical variation in the bark anole *(Anolis distichus)*: microgeographic differentiation among Floridian populations.
KING, R. B., Purdue University.
Enzyme and pattern polymorphism in Lake Erie water snakes.
GREEN, D. M., McMaster University.
Biochemical and cytogenetic evaluation of western North American frogs allied to *Rana aurora* and *R. boylei*.
JENNINGS, R. D., University of New Mexico.
Biochemical variation in the desert tortoise, *Gopherus agassizii*.
GAGE, R. D., University of California, Berkeley.
Genetic variation and relationships among South American iguanid lizards *(Liolaemus, Phymaturus* and *Diplolaemus)*.
FARRIS, J. S. and A. G. Kluge, State University of New York, Stony Brook and University of Michigan.
Genetic distance data: a critical review of published research on amphibian and reptile phylogenetic inference.
BUTH, D. G., University of California, Los Angeles.
Application of electrophoretic data in systematic studies of lower vertebrates: a critique and recommendations.
ROSE, F. L., Texas Technical University.
Lyophilization of tissue homogenates and hemolysates as a method for long-term storage of electrophoretic samples.

SYSTEMATICS VII: AMPHIBIANS AND REPTILES
CHAIRPERSON: WILLIAM E. DUELLMAN

SWEET, S. S., University of California, Santa Barbara.
Species groups within *Pituophis melanoleucus*: evidence from morphology.
MEYLAN, P. A., University of Florida and Florida State Museum.
Evolutionary relationships of Recent trionychid turtles: evidence from shell morphology.
CLARK, J. M., University of Chicago.
Fossil crocodiles of the Early Jurassic Moenave and Kayenta formations of Arizona.
CANNATELLA, D. C., University of Kansas.
Cladistic relationships of pelobatoid and pipoid frogs.
DUTTA, S. K., University of Kansas.
Systematic status of the genus *Tomopterna* (Anura: Ranidae) in Asia, Africa and Madagascar.
DUELLMAN, W. E. and P. M. Ruiz-C., University of Kansas.
Intrapopulation polychromatism in marsupial frogs: an ontogenetic phenomenon.
MOODY, S., Ohio University.
Standardized length measurements and scale counts for lizards: new and improved methods for systematic and population studies.
ETHERIDGE, R., San Diego State University.
The "Leiosaurs" (Reptilia: Iguanidae), and introduction to the group.
CROTHER, B. I., M. M. Miyamoto, and W. Presch, University of Miami and California State University, Fullerton.
A phylogenetic study of the lizard family Xantusiidae.

PHYSIOLOGY I: THERMAL BIOLOGY OF AMPHIBIANS AND REPTILES
CHAIRPERSON: RONALD GRATZ

LAYNE, J. R. JR., Miami University.
Time courses in thermal acclimation in plethodontid salamanders.
SMITH, E. N., N. C. Long, and J. Wood, Hansen Research Foundation, Oberlin College and Caymen Island Turtle Farm, Ltd.
Thermoregulation of sea turtles, *Chelonia mydas*.
SMITH, E. N., N. C. Long, and S. Robertson, Hansen Research Foundation and Oberlin College.
Heat exchange in lizards.
GATTEN, R. E., Jr., University of North Carolina, Greensboro.
Thermal acclimation of aerobic and anaerobic metabolism in lizards.
LANG, J. W., University of North Dakota.
Behavioral fever in the American alligator.
MANIS, M. L., Miami University.
Comparative thermal physiology in *Rana sylvatica*.
HERTZ, P. E. Barnard College, Columbia University.
The use of copper models to evaluate thermoregulation by three *Anolis* lizard species in Puerto Rico.
PAULISSEN, M. A. and C. C. Carpenter, University of Oklahoma.
Thermoregulatory strategy of the six-lined race runner, *Cnemidophorus sexlineatus*, in Oklahoma.
PAULSON, B. K. and V. H. Hutchison, University of Oklahoma.
Critical Thermal Maximum endpoint: the loss of righting response or onset of spasms?

PHYSIOLOGY II: GENERAL PHYSIOLOGY
CHAIRPERSON: LOUIS GUILLETTE, JR.

TAIGEN, T. L., K. D. Wells, and R. L. Marsh, University of Connecticut.
Enzymatic correlates of oxygen consumption in calling spring peepers.
DIAL, B. E., Texas A&M University.
Anaerobic metabolism during nest emergence and the hatchling frenzy in hatchling sea turtles *(Caretta caretta)*.
ADLER, K. and J. B. Phillips, Cornell University.
Orientation in desert lizards: time-compensated use of skylight polarization cues.
TAIGEN, T. L., and C. Busher, University of Connecticut.
Metabolic correlates of the intraspecific variation in toxicity, diet, and habitat of a dart-poison frog, *Dendrobates pumilio*.
FREDA, J., Pennsylvania State University.
Physiological effects of low pH on amphibians.
ROUNTREE, R. L., D. A. Baeyens and A. A. Karlin, University of Arkansas, Little Rock.
A comparative study of the diving biochemistry of reptiles.

PHYSIOLOGY III: GENERAL PHYSIOLOGY
CHAIRPERSON: I. Y. MAHMOUD

MAGNUSSON, W. E. and A. P. Lima, Instituto Nacional de Pesquisias da Amazonia.
Sources of heat for nests of *Paleosuchus trigonatus*.
DUNSON, W. A., Pennsylvania State University.
Estuarine populations of the turtle *Chelydra* as a model for the evolution of marine adaptations in reptiles.
BECK, J. W., Jr., University of Miami.
Aspects of osmoregulation in freshwater turtles.
SCHWENK, K., University of California, Berkeley.
Tongue morphology and prey prehension in iguanid lizards and *Sphenodon*.
GRAVES, B. M., D. Duvall, and M. B. King, University of Wyoming.
Aggregation and water loss among prairie rattlesnakes before and after shedding the proto-integument.
WILLIAMS, E. E., Harvard University.
Lizard skin mechanoreceptors.
FRITZSCH, B., University of Bielefeld, FDR.
The distribution and relevance of electroreception among amphibians.

ECOLOGY II: POPULATION ECOLOGY
CHAIRPERSON: ROYCE E. BALLINGER

BRUCE, R. C., Highlands Biological Station and Western Carolina University.
An ecological life table for the salamander, *Eurycea bislineata*.
VORIS, H. K., Field Museum of Natural History.
Population size estimates for a sea snake, *Enhydrina schistosa*.
NICKERSON, M. A., C. E. Mays, M. D. Tohulka and H. E. Barton, Milwaukee Public Museum, DePauw University, Max Allen Zoological Gardens and Arkansas State University.
Changing chelonian populations in a spring-fed Ozark river.
KNIGHT, J. L., Savannah River Ecology Laboratory.
A mark-recapture study of a tropical colubrid snake, *Tretanorhinus nigroluteus*.

ECOLOGY III: POPULATION & COMMUNITY ECOLOGY
CHAIRPERSON: GARY D. GROSSMAN

HOLOMUZKI, J. R., Arizona State University.
Influence of invertebrate predation on diel patterns of habitat use by larval salamanders.
GUTZKE, W. H. N., Colorado State University.
The influence of the hydric environment during the various periods of development on eggs and hatchlings of painted turtles *(Chrysemys picta).*
CHENG, H. Y., Tulane University.
Resource allocation strategies in *Sphaerodactylus* geckos: a colonizers versus specialists (confiners) selection.
GUYER, C., University of Miami.
Demographic responses of the anoline lizard, *Norops humilis,* to supplemental feedings.
WALTON, M., University of Chicago.
The influence of microclimate on the availability of prey of the salamander, *Plethodon cinerus.*

ECOLOGY IV: LIFE HISTORY OF AMPHIBIANS AND REPTILES
CHAIRPERSON: ROBERT F. CLARKE

WALKER, J. M., and S. E. Trauth, University of Arkansas and Southern Methodist University.
The parthenogenetic whiptail lizard, *Cnemidophorus laredoensis* (Teiidae) in Laredo, Texas.
MUSHINSKY, H. R., University of South Florida.
On the relationship between fire and autecology of *Cnemidophorus sexlineatus.*
MOLL, E. O., B. Groombridge, and J. Vijaya, Eastern Illinois University, IUCN Conservation Monitoring Centre, and Madras Crocodile Bank.
Notes on the natural history and relationships of the Cochin Forest cane turtle.
WOOD, R. C., Stockton State College.
Field studies of the mangrove terrapin *Malaclemys terrapin rhizophorarum* in the Florida Keys.
SAUGEY, D. A., U.S. Forest Service.
Observations on a population of slimy salamanders, *Plethodon glutinosus glutinosus* (Green) from the Ouachita Mountains of Arkansas.
STEWART, M. M., State University of New York, Albany.
The flying frogs of Puerto Rico.
LOHOEFENER, R., Mississippi State University Research Center.
The status of the gopher tortoise *(Gopherus polyphemus)* in Mississippi.
BERRY, K. H. and F. B. Turner, Bureau of Land Management and University of California, Los Angeles.
The behavior of juvenile desert tortoises *(Gopherus agassizii).*
ECHTERNACHT, A. C., University of Tennessee.
***Anolis carolinensis* (Sauria: Iguanidae) in east Tennessee at the northern margin of the range of the species and the genus.**

ECOLOGY V: FORAGING ECOLOGY
CHAIRPERSON: MICHAEL PLUMMER

FEDER, M. E. and P. L. Londos, University of Chicago.

PREDATOR-PREY RELATIONSHIPS IN LOWER VERTEBRATES SYMPOSIUM Back row, from left to right: G. Roth, G. V. Lauder, E. E. Werner, S. J. Arnold, J. A. Endler, P. W. Webb, M. E. Feder. Front row: R. B. Huey, C. Gans, G. S. Helfman, A. F. Bennett.

Hydric constraints upon foraging in a terrestrial salamander, *Desmognathus.*
JAEGER, R. G., University of Southwestern Louisiana.
Choice of diet by the salamander *Plethodon cinereus* in a natural habitat.
BART, H. L. and R. W. Holzenthal, University of Oklahoma and University of New Orleans.
Feeding of the Gulf Coast waterdog, *Necturus beyeri,* and its indications on the ecology of the species.
MILLER, D. E., University of South Florida.
Foraging of the mangrove water snake, *Nerodia fasciata compressicauda.*
GREENE, H. W. and M. A. Santana, University of California, Berkeley and Universidad de Costa Rica.
Diet and hunting behavior in free-living bushmasters *(Lachesis muta,* Viperidae).
CUNDALL, D., Lehigh University.
Feeding behavior in the primitive snake, *Cylindrophis rufus.*
WALDSCHMIDT, S. R. and S. M. Jones, University of Wisconsin.
The effect of body temperature and the rate of food consumption on the probability of feeding and passage rate in the lizard, *Sceloporus undulatus.*
JONES, S. M., University of Wisconsin.
Between-year variability in the reproduction of the iguanid lizard, *Sceloporus undulatus:* environmental sources of variation.
FLORES—VILLELA, O. A. and R. C. Vogt, Universidad Nacional Autonoma de Mexico.
Food habits and morphometrics of the "chopontil" *Claudius angustatus* in Veracruz, Mexico.

ECOLOGY VI: COMMUNITY ECOLOGY
CHAIRPERSON: MARY POWER

SOUTHERLAND, M. T., University of North Carolina.
Interspecific interactions among four species of *Desmognathus* salamanders.
NISHIKAWA, K. C., University of North Carolina and Dalhousie University.
The evolution of interspecific aggression among plethodontid salamanders.
TAYLOR, J., University of New Hampshire.
Do *Taricha granulosa* and paedomorphic *Ambystoma gracile* compete? Some problems with theory.

ECOLOGY VII: GENERAL ECOLOGY
CHAIRPERSON: RAY DRENNER

GILLINGHAM, J. C., Central Michigan University.
Snake predation and the cost of lizard territoriality.
JACKSON, D. R., Florida Natural Areas Inventory, The Nature Conservancy.
Predation on turtles by the American alligator: ecological and morphological correlates.
SNOW, J. E., University of Oklahoma.
Diets of juvenile turtles *(Chrysemys)* in experimental pond enclosures: Phylogenetic and ontogenetic variation.
GUZMAN GUZMAN, S. and R. C. Vogt, Universidad de Veracruz and Universidad Nacional Autonoma de Mexico.
Food partitioning in three species of neotropical freshwater turtles in southern Veracruz, Mexico.
KIND, M. B. and D. Duvall, University of Wyoming.
Foraging decisions by the prairie rattlesnakes in a patchy habitat: preliminary decisions.
SIEGEL, R. A., Savannah River Ecology Laboratory.
Seasonal variations in the foraging ecology of two species of garter snakes.
NOVAK, S. S., R. A. Siegel, S. W. Oliver and J. L. Knight, Savannah River Ecology Laboratory.
Movement responses of American alligators to thermal effluents.

ECOLOGY IX: ECOLOGY OF AMPHIBIANS & REPTILES
CHAIRPERSON: STANLEY F. FOX

BERGER, T. J., University of Kansas.
Patterns of tadpole biomass density in a permanent, temperate pond.
KRUPA, J. J. and J. E. Snow, University of Oklahoma.
Phylogenetic variation in spatial distributions of hatchling turtles *(Chrysemys)* in an experimental pond enclosure.
TURNER, F. B. and K. H. Berry, University of California, Los Angeles and Bureau of Land Management.
Population dynamics of the desert tortoise *(Gopherus agassizii)* in the eastern Mojave Desert.
MOLL, D. L., Southwest Missouri State University.
The status and distribution of *Dermatemys mawei* in Belize.
CHOO, B. L. and L. M. Chou, National University of Singapore.
Effect of photoperiod on the growth and survival of soft-shelled turtle, *Trionyx sinensis*, hatchlings.
SCUDDER, R. M. and G. M. Burghardt, Wabash College.
The effect of the feeding regimen on the growth of neonate broad-banded water snakes, *Nerodia fasciata confluens* (Colubridae), and its possible effect on reproduction.
McALLISTER, C. T., S. E. Trauth and J. Ubelaker, Veterans Administration Medical Center, Dallas and Southern Methodist University.
Food habits and endoparasites of *Crotophytus collaris collaris* (Sauria: Iguanidae), with a description of a new tapeworm species.

ZOOGEOGRAPHY
CHAIRPERSON: GLENN KLEMMER

WHITE, B., Los Angeles County Museum of Natural History.
Speciation and the environment: a new look at global diversity patterns.
HOCUTT, C. H., and R. L. Tilney, University of Maryland and Rhodes University, South Africa.
Drift of India: a vicariant event.
HENDRICKSON, D. A., Arizona State University.
Suspect terranes, suspicious salamanders and New World biogeography.

REPRODUCTIVE BIOLOGY I: SEX RATIOS & REPRODUCTIVE STRATEGIES
CHAIRPERSON: FRANKLIN SNELSON, JR.

BENABIB-NISENBAUM, M. and R. C. Vogt, Universidad Nacional Autonoma de Mexico.
Environmental sex determination in *Dermochelys coriacea* on natural nesting beaches—significance of nest position and laying date.
VOGT, R. C., Universidad Autonoma de Mexico.
Reproductive strategies of neotropical fresh water turtles: tropical endemics vs. temperate zone invaders.
HOWARD, R. D. and A. G. Kluge, Purdue University and University of Michigan.
Sexual selection and patterns of reproductive success (RS) in woodfrogs *Rana sylvatica*.
HOUCK, L. D., S. J. Arnold and R. A. Thisted, University of Chicago.
Variation in mating success in the plethodontid salamander, *Desmognathus ochrophaeus*.
GUTZKE, W. H. N., G. L Paukstis and L. L. McDaniel, Colorado State University.
Skewed sex ratios for adult and hatchling bullsnakes, *Pituophis melanoleucas*, in Nebraska.

LARVAL BIOLOGY I: AMPHIBIANS
CHAIRPERSON: ROBERT JAEGER

ALBERCH, P., Harvard University.
Cartilage remodeling during the metamorphosis of the plethodontid salamander, *Eurycea bislineata*.
WASSERSUG, R. J., K. Hoff, and K. C. Nishikawa, Dalhousie University.
Kinematics of swimming in *Rana* and *Xenopus* larvae.
HOFF, K., R. J. Wassersug and K. C. Nishikawa, Dalhousie University.
Gross morphology and passive mechanical properties of the tails of *Rana* and *Xenopus* larvae.
NISHIKAWA, K. C., K. Hoff, and R. J. Wassersug, Dalhousie University.
Neuromuscular control of swimming in *Rana* and *Xenopus* tadpoles.
SCHMIDT, F. and T. J. Berger, University of Kansas.
Sprint velocity and morphology of *Rana catesbelana* tadpoles.
TRAVIS, J., Florida State University.
Genetic analysis of growth and development patterns in larval anurans.
SEMLITSCH, R. D., Savannah River Ecology Laboratory.
Environmental and genetic components of metamorphosis and paedomorphosis in *Ambystoma talpoideum*.
LANNOO, M. J., Dalhousie University.
Systematic and ecological considerations of neuromast topography in *Ambystoma* larvae.
da ROCHA, C. F., W. E. Magnusson and A. P. Lima, Universidad de Rio de Janeiro, Brasil.
Palatability of tadpoles of Amazonian forest frogs.
KAPLAN, R. H., Reed College.
Factors that affect metamorphosis: embryo size and food level.
BEMIS, W. E., University of Chicago.
Developmental functional morphology of feeding in the salamander, *Taricha torosa*.

LARVAL BIOLOGY II: FISHES AND AMPHIBIANS
CHAIRPERSON: F. DOUGLAS MARTIN

COLLINS, J. P., Arizona State University.
Paedomorphosis and the evolution of morphological variation in *Ambystoma tigrinum*.
NELSON, C. E. and I. H. Jaafar, Indiana University.
Calorimetric analysis of eggs and metamorphs for seven amphibian species.

MORPHOLOGY I
CHAIRPERSON: THEODORE PAPENFUSS

MILLER, K., P. B. Pinto and L. F. Landis, Franklin and Marshall College.
Why big frogs jump farther than small frogs.
SESSIONS, S. K., University of California, Berkeley.
Mechanisms of morphogenesis in ontogeny and phylogeny: evidence from limb regeneration in plethodontid salamanders.
HANKEN, J. and B. K. Hall, University of Colorado and Dalhousie University.
Variation and timing of the cranial ossification sequence of the Oriental fire-bellied toad, *Bombina orientalis*.
PETERSON, C. R., S. J. Arnold and J. S. Tsuji, University of Chicago and University of Washington.
The effect of temperature on growth in *Thamnophis sirtalis*.
STEWART, J. R., University of Tulsa.
Structure of the fetal membranes of *Gerrhonotus multicarinatus* and *Gerrhonotus coeruleus*.

WANTED

OLD — RARE — O.P.

Herpetology

Large and Small Collections of Natural History Books Purchased

John Johnson

North Bennington R.F.D. 2 Vermont

05257

MORPHOLOGY II
CHAIRPERSON: KIRK MILLER

BRAMBLE, D. M., University of Utah.
Engineering and evolutionary implications of chelonian shell architecture.
PETERSON, J. A. and R. L. Bezy, Los Angeles County Museum of Natural History.
Scale micro-architecture of xantusiid lizards.
PETERSON, J. A., Los Angeles County Museum of Natural History.
The micro-architecture of the scales of iguanid lizards.
TRAUTH, S. E., W. E. Cooper and L. J. Vitt, Southern Methodist University, Auburn University and University of California, Los Angeles.
Cloacal anatomy and glands of the broad-headed skink, *Eumeces laticeps*.

BEHAVIOR I: COMMUNICATION OF AMPHIBIANS & REPTILES
CHAIRPERSON: DAVID DUVALL

THORNHILL, G. M., Ohio University.
Hearing threshold and sound propagation in Fowler's toad.
FORESTER, D. C. and W. H. Harrison, Towson State University.
The significance of non-overlapping, synchronous vocalization by the spring peeper, *Hyla crucifer*.
WELLS, K. D. and T. L. Taigen, University of Connecticut.
Energetics of vocalization by an anuran amphibian *(Hyla versicolor)*.
SULLIVAN, B. K., Arizona State University.
Advertisement call variation and observations on breeding behavior of five anurans (*Scaphiopus* and *Bufo*) in southern Arizona.
SULLIVAN, B. K., Arizona State University.
Male calling behavior in response to playback of conspecific advertisement calls in two bufonids of Arizona.
BISHOP, P. J., University of Witwatersrand, South Africa.
Comparative analysis of chorus organization of some African anurans.
LOSOS, J. B., Harvard University.
The importance of dewlap color for species recognition in the sympatric sibling species, *Anolis marcanoi* and *Anolis cybotes*.
DUVALL, D., M. B. King, K. Gutzwiller and B. M. Graves, University of Wyoming.
Assessment and defensive escalation in prairie rattlesnakes: effects of social and habitat context.
VLIET, K. A., University of Florida.
Bellows and headslaps: social displays of the American alligator.
SECOR, S. M., University of Oklahoma.
An analysis of the reproductive behavior of the speckled kingsnake, *Lampropeltis getulus holbrooki*.
CARPENTER, G. C., University of Wyoming.
Behavioral ecology of the western banded gecko *(Coleonyx variegatus)* at defecation sites in southern California.
DAWLEY, E. M., University of Connecticut.
Olfactory communication in salamanders: identifying sex, species, and ploidy level through chemical cues.

BEHAVIOR II: AMPHIBIANS AND REPTILES
CHAIRPERSON: JAMES C. GILLINGHAM

RODDA, G. H., University of Tennessee.
Magnetic sensitivity in navigating alligators.
FERRIS, J. S. and H. Gucinski, Ecological-Analysts, Inc. and Anne Arundel Community College.
Role of measured light intensities in successful seaward orientation of hatchling loggerhead turtles *Caretta caretta*.
Dunham, A. E. and B. W. GRANT, University of Pennsylvania.
Biophysical constraints of the activity of the lizard *Sceloporus merriami*.
CRUMP, M. L., University of Florida.
Site fidelity and homing in *Atelopus varius*.
RUBY, D. E. and A. E. Dunham, Drexel University and University of Pennsylvania.
Alternate behavioral strategies in use of space in male lizards *Sceloporus merriami*.
FOX, S. F., N. R. Rachuk, and L. A. DeLay, Oklahoma State University.
The social cost of tail loss in the lizard *Uta stansburiana*: body injury vs. loss of length.
BOWKER, R. W., Arizona State University.
Agonistic and courtship behavior of the Arizona alligator lizard, *Gerrhonotus kingi*.
CLARK, D. L., Central Michigan University.
Sleep site fidelity in Puerto Rican anoline lizards.
JAYNE, B. C., Michigan State University.
A graphical approach for analyzing modes of snake locomotion.

REPRODUCTIVE BIOLOGY II
CHAIRPERSON: RONALD BRANDON

FRAZER, N. B. and J. I. Richardson, Woods Hole Oceanographic Institute and University of Georgia.
Reproductive variation in loggerhead turtles, *Caretta caretta*.
IVERSON, J. B., Earlham College.
Geographic variation in reproduction in the mud turtle *Kinosternon flavescens*.
FITCH, H. S., University of Kansas.
Geographic variation in clutch and litter size in American reptiles.
WALLS, S. C. and R. G. Altig, University of Southwestern Louisiana and Mississippi State University.
The female reproductive biology of the marbled salamander, *Ambystoma opacum*, in Mississippi.
HOWLAND, J. M., University of California, Los Angeles.
The reproductive biology of the iguanid lizard *Cophosaurus texanus* in Big Bend National Park, Texas.
ROBLE, S. M., University of Kansas and Carnegie Museum of Natural History.
The reproductive and population ecology of *Hyla chrysoscelis*.

REPRODUCTIVE BIOLOGY III: REPRODUCTIVE PHYSIOLOGY
CHAIRPERSON: JAMES R. STEWART

MITCHELL, J. C., University of Richmond.
Variation in male reproductive cycles in syntopic populations of *Chrysemys picta* and *Sternotherus odoratus* from Virginia.
SEVER, D., St. Mary's College.
Sexually dimorphic glands of *Eurycea nana*, *Eurycea neotenes* and *Typhlomolge rathbuni* (Amphibia).
GUILLETTE, L. J., Jr. and S. L. Fox, Wichita State University.
Effect of deluteinization on plasma progesterone concentration and gestation in the lizard, *Anolis carolinensis*.
FOX, S. L., Wichita State University.
Luteal histology and plasma progesterone concentration in two lizard species.
MENDONCA, M. T., University of California, Berkeley.
Hormone fluctuations and behavior in a field population of calling male bullfrogs.
LONG, D. R., Texas Technical University.
Fat body distribution in *Bufo cognatus*.

BIOLOGY OF *CNEMIDOPHORUS* SYMPOSIUM SPEAKERS Back row, left to right: D. Crews, M. C. Moore, F. H. Van Berkum, R. A. Anderson, C. J. Cole, B. E. Leuck, J. A. Moreno, K. Etheridge. Middle row: C. H. Lowe, H. C. Dessauer, S. E. Trauth, E. D. Parker Jr., L. J. Vitt, L. C. Wit, M. S. Rand, G. Casas-Andrew, J. M. Walker. Front row: R. G. Zweifel, T. Garland Jr., J. J. Schall, J. W. Wright, L. D. Densmore, A. H. Price, J. F. Scudday, R. G. Bowker, B. G. Hanks.

REPRODUCTIVE BIOLOGY IV:
CHAIRPERSON: HARRY W. GREENE

MASON, R. T., University of Texas.
Female mimicry in the garter snake, *Thamnophis sirtalis parietalis.*
SELCER, K. W., Texas Technical University.
Maternal investment in a lizard with a fixed clutch size.
PETOKAS, P. J., State University of New York, Binghamton.
Nesting ecology and reproductive effort in Blanding's turtle, *Emydoidea blandingii.*
HAYES, M. P., University of Miami.
The ecology of clutch attendance in the tropical frog, *Centrolenella fleischmanni.*
EWERT, W. A., Indiana University.
Relative clutch mass of turtles.
STEWART, J. R. and J. L. Vial, University of Tulsa.
Sexual dimorphism in a tropical gerrhonotine lizard.
WOOLBRIGHT, L. L., State University of New York, Albany.
Sex-specific energy budgets predict size dimorphism for *Eleutherodactylus coqui* (Anura: Leptodactylidae).
STAUB, N., University of California, Berkeley.
Sexual dimorphism in *Aneides hardii.*
GERHARDT, H. C., R. E. Daniel, and S. A. Perrill, University of Missouri and Butler University.
Male mating behavior in *Hyla cinerea.*
REAGAN, N. L., Western Carolina University.
Courtship behavior of the *Eurycea bislineata wilderae* complex.
VERRELL, P. A., The Open University, England.
Mating decisions of male red-spotted newts, *Notophthalmus viridescens.*
ROSTKER, M. A., U.S. Environmental Protection Agency.
Female mate choice in collared lizards: intrinsic quality or territory quality.

SPECIAL INVITED ADDRESSES
CHAIRPERSON: KRAIG ADLER

PROFESSOR ERMI ZHAO, Chengdu Institute of Biology, Chengdu, Sichuan, China.
A brief review of the amphibians and reptiles of China.
PROFESSOR KUANG YANG LUE, National Taiwan Normal University, Taipei, Taiwan, China.
The amphibians of Taiwan (Formosa).

SYMPOSIUM: PREDATOR-PREY RELATIONSHIPS IN LOWER VERTEBRATES I. PHYSIOLOGY & MORPHOLOGY
CHAIRPERSON: MARTIN E. FEDER

FEDER, M. E. and G. V. Lauder, University of Chicago.
INTRODUCTION: Predator-prey relationships in lower vertebrates: I. Physiology and morphology.
BENNETT, A. F., University of California, Irvine.
Measuring behavioral energetics.
ROTH, G., University of Bremen, FDR.
Sensory physiology and neuroethology of predator-prey relationships.
GANS, C., University of Michigan.
Functional morphology as a tool in the study of predator-prey interactions.
WEBB, P. W., University of Michigan.
Locomotion and predator-prey relationships.

SYMPOSIUM: PREDATOR-PREY RELATIONSHIPS IN LOWER VERTEBRATES II. ECOLOGY & BEHAVIOR
CHAIRPERSON: GEORGE V. LAUDER

LAUDER, G. V. and M. E. Feder, University of Chicago.
INTRODUCTION: Predator-prey relationships in lower vertebrates: II. Ecology and behavior.
HUEY, R. B., University of Washington.
Combined field and laboratory approaches to the study of predation.
HELFMAN, G. S., University of Georgia.
Behavioral interactions of predators and prey.
WERNER, E. E., Kellogg Biological Station.
Foraging theory and the prediction of predator choice in lower vertebrates.
ENDLER, J. A., University of Utah.
Anti-predator mechanisms.
ARNOLD, S. J., University of Chicago.
The population biology of predator-prey relationships.

SYMPOSIUM: BIOLOGY OF CNEMIDOPHORUS I.
CHAIRPERSON: JOHN W. WRIGHT

WRIGHT, J. W., Los Angeles County Museum of Natural History.
INTRODUCTION. (Includes eulogy of T. Paul Maslin given by C. J. McCoy, Carnegie Museum).
WRIGHT, J. W. and D. A. Good, Los Angeles County Museum of Natural History and University of California, Berkeley.
Allozymes and evolution in the genus *Cnemidophorus.*
PARKER, E. D., Jr., McNeese State University.
Biogeographic implications of clonal diversity in parthenogenetic species of *Cnemidophorus.*
GOOD, D. A. and J. W. Wright, University of California, Berkeley and Los Angeles County Museum of Natural History.
Allozymes and the origin of the parthenogenetic members of the *Cnemidophorus sexlineatus* species group.
COLE, C. J. and H. C. Dessauer, American Museum of Natural History and Louisiana State University Medical Center.
Clonal inheritance in parthenogenetic species of lizards.
BROWN, W. M., J. W. Wright and L. D. Densmore, University of Michigan and Los Angeles County Museum of Natural History.
Mitochondrial DNA and evolution in *Cnemidophorus.*
DENSMORE, L. D., J. W. Wright and W. M. Brown, University of Michigan and Los Angeles County Museum of Natural History.
Mitochondrial DNA and the evolution of a parthenogenetic complex of lizards *(Cnemidophorus).*
WALKER, J. M., University of Arkansas.
The species groups, and subspecies of *Cnemidophorus* (Teiidae): a critical inventory.

SYMPOSIUM: BIOLOGY OF *CNEMIDOPHORUS* II.
CHAIRPERSON: LAURIE J. VITT

LOWE, C. H., University of Arizona.
Cnemidophorology and cnemidophorologists—the genus *Cnemidophorus* 155, 55, and 33 years later.
HANKS, B. G. and J. F. Scudday, Texas A&M University and Sul Ross State University.
Allozyme electrophoresis in *Cnemidophorus gularis* S.L. from the Chihuahuan Desert region.
DESSAUER, H. C. and C. J. Cole, Louisiana State University Medical Center and American Museum of Natural History.
Genetics of *Cnemidophorus tigris* populations in a contact zone in New Mexico.
MORENO, J. A., University of Miami and Department of Natural Resources, Puerto Rico.
Morphological character variation, heterozygosity and genome coadaption in *Cnemidophorus* (Sauria: Teiidae).
TRAUTH, S. E. and W. R. Fagerberg, Southern Methodist University.
Morphometric analysis of eggshell structure in *Cnemidophorus laredoensis* and *C. sexlineatus.*
GARLAND, T., Jr., University of California, Irvine.
Locomotory performance and activity metabolism of *Cnemidophorus tigris* in relation to natural behaviors.
BOWKER, R. G., Alma College.
The thermoregulation of the lizards *Cnemidophorus velox* and *C. exsanquis:* some consequences of high body temperatures.
ETHERIDGE, K. and L. C. Wit, University of Florida and Auburn University.
Factors affecting activity in *Cnemidophorus.*
WIT, L. C. and J. C. Sellers, Auburn University.
Physiological regulation of hibernation in *Cnemidophorus sexlineatus:* possible role of the thyroid.
CREWS, D., J. Whittier, A. Billy and M. C. Moore, University of Texas and Arizona State University.
Male-like behavior in an all-female lizard: relationship to ovarian cycle.
MOORE, M. C., J. M. Whittier and D. Crews, Arizona State University and University of Texas.
Sex steroid hormones during the ovarian cycle of the parthenogenetic whiptail lizard, *Cnemidophorus uniparens:* relationship to male-like behavior.
VAN BERKUM, F. H., University of Washington.
Thermal sensitivity of locomotion in *Cnemidophorus* and *Ameiva.*

SYMPOSIUM: BIOLOGY OF *CNEMIDOPHORUS III.*
CHAIRPERSON: JOSEPH J. SCHALL

LEUCK, B. E., Centenary College of Louisiana.
Comparative social behavior of *Cnemidophorus:* the role of bisexuality, parthenogenesis and ploidy level.
ANDERSON, R. A., University of California, Los Angeles.
Foraging of *Cnemidophorus tigris* as a function of prey availability.

RAND, M. S., R. M. Storm and J. J. Beatty, Wichita State University and Oregon State University.
A population of parthenogenetic *Cnemidophorus* in central Oregon: in support of the weed hypothesis.
SCHALL, J. J., University of Vermont.
Plant secondary compounds and the diet of the herbivorous whiptail lizard, *Cnemidophorus arubensis.*
CASAS-ANDREAU, G. and M. A. Gurrola-Hidalgo, Universidad Nacional Autonoma de Mexico.
Aspects of the comparative ecology of two species of *Cnemidophorus* in coastal Jalisco, Mexico.
PRICE, A. H., New Mexico State University.
Competition and parthenogenesis in *Cnemidophorus:* ecological aspects and evolutionary implications.
VITT, L. J. and G. L. Breitenbach, University of California, Los Angeles.
Life histories and reproductive strategies among species within the genus *Cnemidophorus.*
WRIGHT, J. W.
SUMMARY.

SSAR ZOO LIAISON COMMITTEE SYMPOSIUM: MANAGEMENT OF ENDANGERED REPTILES AND AMPHIBIANS IN CAPTIVITY.

CHAIRPERSON: PETER J. TOLSON

HUDSON, R. D., Fort Worth Zoological Gardens.
The species survival plan and its application to reptiles.
QUINN, H., K. Peterson and A. Odum, Houston Zoological Gardens.
Genetic and demographic management of small, captive populations of endangered reptiles and amphibians with special emphasis on management of *Crotalus unicolor.*
DENSMORE, L. D. and H. C. Dessauer, University of Michigan and Louisiana State University Medical Center.
The "absence" of protein divergence in *Crocodylus*—a slowdown in the rate of molecular evolution or a recent radiation.
BELCHER, A. D. and H. E. Lawler, Rio Grande Zoological Garden and Arizona-Sonora Desert Museum.
A cooperative propagation project for the protected rattlesnakes of Arizona.
REYNOLDS, R. P., U.S. Fish and Wildlife Service and U.S. National Museum.
Status of the Galapagos tortoise *(Geochelone elephantopus)* and a review of the captive breeding program at the Charles Darwin Station.
LAWLER, H. E., Arizona-Sonora Desert Museum.
Captive management of the endangered Isla San Esteban chuckwalla, *Sauromalus varius* (Sauria: Iguanidae) at the Arizona-Sonora Desert Museum.

REGIONAL HERPETOLOGICAL SOCIETIES CONFERENCE. MONITORING REPTILE AND AMPHIBIAN POPULATIONS: AN IMPORTANT ROLE FOR REGIONAL HERPETOLOGICAL SOCIETIES.

CHAIRPERSON: JEFFREY H. BLACK

PLUMMER, M., Harding University.
Monitoring of reptile populations by mark-recapture.
SEMLITSCH, R., Savannah River Ecology Laboratory.
Monitoring amphibian populations: qualitative and quantitative approaches.
SECOR, S. M. and C. C. Carpenter, University of Oklahoma.
The DOKARRS system: a method to accumulate natural history and distribution accounts of Oklahoma amphibians and reptiles.
HAMMACK, S.
Description of reptiles and amphibians around Dallas, Texas.

SSAR ZOO LIAISON COMMITTEE SYMPOSIUM Back row, left to right: R. D. Hudson, H. Quinn, H. E. Lawler, A. D. Belcher, Front row: L. D. Densmore, P. J. Tolson, R. P. Reynolds.

POSTERS

NICOLLETO, P. F., Virginia Polytechnic Institute and State University.
The role of vision and olfaction in prey detection by *Scincella lateralis.*
WOOD, R. C., Stockton State College.
Field studies of the side-necked turtle *Pelusios adansonii* in Lake Turkana, Kenya.
HARDING, J. H., Cranbrook Institute of Science.
The wood turtle *(Clemmys insculpta)* and its predators: Comments on survival after mutilation.
EHRHART, L. M., University of Central Florida.
Structure and status of the loggerhead and green turtle populations in the central region of Indian River, Florida.
LORAINE, R. K., University of Kansas and Savannah River Ecology Laboratory.
Distribution and habitat preferences of the wood turtle, *Clemmys insculpta*, in Iowa.
PECHMANN, J. H. K. and R. L. Schneider, Savannah River Ecology Laboratory.
The spatial distribution of migrating amphibians around two breeding sites.
BOCK, B. C., A. S. Rand, and G. M. Burghardt, University of Tennessee, Knoxville and Smithsonian Tropical Research Institute.
Radio-telemetry investigations of nesting movements in green iguanas.
HERNANDEZ, J. O., G. Casas-Andreu and J. W. Wright, Unicoma, Mexico, Instituto de Biologia, UNAM, Mexico and Los Angeles County Museum of Natural History.
La herpetofauna de Mexico. (video)
MULVANY, P. S., Oklahoma Herpetological Society.
Possible climatic controls on the biogeography of blind snakes in the United States.
OSBORNE, S. T., Oklahoma City Zoo.
Some aspects of reproductive biology in the beaded lizard, *Heloderma suspectum.* (video)
CENSKY, E. J. and C. J. McCoy, Carnegie Museum of Natural History.
Reproduction in *Bothrops yucatanicus* (Crotalidae).
BEAUCHAT, C. A. and E. J. Braun, University of Arizona.
Renal morphology of a neonatal lizard, *Sceloporus jarrovi.*
STOVALL, R. H., Valencia Community College.
Pits, papillae, and scales: Light and scanning electron microscope observations of squamate skin.
JASLOW, A. P., R. E. Lombard and T. E. Hetherington, University of Chicago and Ohio State University.
Hearing and middle ear structure in anurans.
WILHOFT, D. C., Rutgers University.
Posthatching yolk components and utilization in the snapping turtle, *Chelydra serpentina.*
RAYMOND, P. W., University of Central Florida.
Sea turtle hatchling disorientation and artificial beachfront lighting: a review of the problem and potential solutions.
KREMPELS, D. M., University of Miami.
Near infrared reflectancy by coral snakes: aposematic coloration?

REGIONAL HERPETOLOGICAL SOCIETIES CONFERENCE Left to right: J. H. Black, R. Semlitsch, S. M. Secor, C. C. Carpenter, S. Hammack.

FRITTS, T. H. and R. D. Jennings, U.S. Fish & Wildlife Service and University of New Mexico.
Variation in the expression of maternal protection in the American alligator, *Alligator mississippiensis*.
COOPER, W. E. and L. J. Vitt, Auburn University at Montgomery and University of California, Los Angeles.
Interspecific odor discrimination by the broad-headed skink, *Eumeces laticeps*.
SMITH, E. N., N. C. Long and J. Wood, Hansen Research Foundation, Oberlin College and Caymen Island Turtle Farms, Ltd.
Evaporative water loss in the green sea turtle, *Chelonia mydas*.
COSTANZO, J. P., Michigan Technological University.
The bioenergetics of hibernation in the eastern garter snake, *Thamnophis s. sirtalis*.
DePARI, J. A., Rutgers University.
Overwintering of *Chrysemys picta* hatchlings in the nest chamber in northern New Jersey.
HOTALING, E. C., Rutgers University.
Fluctuating and constant incubation temperatures: their effect on sex ratios in *Chelydra* and *Malaclemys*.
HUTCHISON, V. H. and K. Spriestersbach, University of Oklahoma.
Diel and seasonal cycles in thermal selection in *Necturus maculosus*.
POWELL, G. L. and A. P. Russell, University of Calgary.
Growth and allometry in *Phrynosoma douglassi*.
GIBSON, A. R., D. A. Smucny and J. Kollar, Cleveland State University.
Thermal biology of young common garter snakes, *Thamnophis sirtalis*.
GRATZ, R. K., Michigan Technological University.
The effect of vagal input in the control of breathing in snakes, *Nerodia sipedon*.
MEADE, L., Morehead State University.
Kentucky snakes: Recent research concerning their systematics and distribution.
FITZGERALD, L. A., and N. J. Scott, Jr., University of New Mexico and U.S. Fish & Wildlife Service.
Taxonomic status of *Hyla sanborni* and *Hyla nana* (Hylidae: Anura).
SEIDEL, M. E., Marshall University.
Revision of the West Indian trachemyd turtles (Testudines: Emydidae).
SIMMONS, J. E., University of Kansas.
A method for preparation of anuran osteological material.
KEEN, W. H. and R. W. Reed, State University of New York College, Cortland.
Defense of cover sites and feeding sites by a plethodontid salamander.
EVANS, D., IUCN Conservation Monitoring Centre, Cambridge, United Kingdom.
Information for conservation.
BUSACK, S. D., University of California, Berkeley.
Biochemical divergence in a Mediterranean herpetofauna.
BAUER, A. M., University of California, Berkeley.
Studies on the functional morphology of gekkonid lizards.
WAKE, D. B. and K. P. Yanev, University of California, Berkeley.
Speciation in the salamander genus *Ensatina*.
SEIB, R. L., University of California, Berkeley.
Feeding ecology of tropical snakes.
WAKE, D. B., T. J. Papenfuss, J. F. Lynch and P. Elias, University of California, Berkeley.
Salamander transect studies in Mexico and Guatemala.
CAROTHERS, J. H., University of California, Berkeley.
Determinants of altitudinal zonation: assemblage structure of *Liolaemus* lizards in the Cordillero of Chile.
PAPENFUSS, T. J., University of California, Berkeley.
The two-legged mole lizards *(Bipes)* of Mexico.
LARSON, A. and D. B. Wake, University of California, Berkeley.
A molecular phylogenetic perspective on the morphological evolution in salamanders of the *Bolitoglossa* beta group.
de QUEIROZ, K., University of California, Berkeley.
Phylogenetic relationships among iguanine squamates.
RAINEY, W. E., University of California, Berkeley.
An ancient gene duplication in reptile serum albumins.
SCHWENK, K., University of California, Berkeley.
Comparative surface morphology of the lizard tongue.
GREENE, H. W., University of California, Berkeley.
Ecological correlates of venom types in snakes.
WAKE, M. H., University of California, Berkeley.
Comparative morphology of the eyes of caecilians.
SNOW, J. E., University of Oklahoma.
Energy acquisition by juvenile turtles *(Chrysemys)*: Test of a prey selection model.
MACEY, R., University of California, Santa Cruz.
The biogeography of a herpetofauna transition between the Great Basin and Mojave Deserts.
WADE, J. K., A. C. Echternacht and G. McCracken, Pennsylvania State University and University of Tennessee.
Genetic variation in *Anolis carolinensis* with red and gray dewlaps.
TELFORD, S. R., III., The Johns Hopkins University.
Why baby snakes aren't cute, or, a saltational origin of snakes.

SSAR COMMITTEES FOR 1984-1985:

Following the Norman meeting, President Gans appointed the following committees, coordinators and representatives to report to the Board of Directors at the Tampa meeting in August of 1985. Individuals with important matters pertaining to these activities should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of *Herpetological Review*.

Grants-in-Herpetology: James P. Bacon (Ch), Thomas H. Fritts, John B. Iverson, Robert W. Murphy, Diane Secoy, Harry Greene, Michael V. Plummer.

Conservation: Patricia Riexinger (Ch), John L. Behler, William S. Brown, C. Kenneth Dodd, Jr., Rene E. Honegger, Paul E. Moler.

Kennedy Student Award: J. Eric Juterbock (Ch), Robert E. Gatten, Jr., Ken R. Marion, John S. Mecham, Laurie J. Vitt.

Nominating: Douglas H. Taylor (Ch), Joseph C. Mitchell, James B. Murphy, Lynne Houck, Martin J. Rosenberg.

Regional Society Liaison: Terry Hibbitts (Ch), H. Bernard Bechtel, Harold DeLisle, James D. Fawcett, John Simmons, Tom Vermersch, George D. Whitney.

Zoo Liaison: Peter J. Tolson (Ch), Jonathan A. Campbell, David Barker, Joseph Laszlo, Ruth Zantzinger, Dale Belcher, James C. Gillingham, Hugh Quinn.

Long-range Planning: James L. Christiansen (Ch), Kraig Adler, Ralph W. Axtell, James S. Jacob, Linda Maxson, Henri C. Seibert.

Meetings (SSAR/HL): Max A. Nickerson (Ch), Ray E. Ashton, Jr., William Cooper, Jr., Victor H. Hutchison, James S. Jacob, C. J. McCoy.

Resolutions (SSAR/HL): Robert A. Thomas (Ch), Others to be appointed at Tampa meeting.

Ad Hoc Career Pamphlet Committee: Neil B. Ford, Martin J. Rosenberg, Henri C. Seibert.

Common and Scientific Names Coordinator: Joseph T. Collins.

Translations Coordinator: Robert D. Aldridge.

Representative to Association of Systematic Collections: Max A. Nickerson.

SSAR Secretary ●

LETTERS TO THE EDITOR

EDITOR:

If evolution is an ongoing, dynamic process, at what point in the study of herpetology are herpetologists going to evolve some compassion for the animals they study?

I have just read a paper in a recent issue (Vol. 40, No. 2) of **Herpetologica** that left me more infuriated than informed. I refer to the paper by Diller and Wallace (pp. 182-193) entitled "Reproductive Biology of the Northern Pacific Rattlesnake *(Crotalus viridis oreganus)* in Northern Idaho," in which they state that "All captured snakes [numbering 387] were taken to the laboratory and immediately frozen, except for 21 juvenile snakes that were marked and released." The brackets above are mine—the number, theirs.

The 387 rattlesnakes sacrificed in their study represent three hibernacula over a 4-year period. They further state that "Other hibernacula were visited during the course of the study, but they contributed only minor numbers of snakes." Since it is common knowledge among interested people that rattlesnakes are especially vulnerable at their hibernacula, it is reasonable to assume that *none* of those visited hibernacula will any longer produce many snakes. These two gentlemen may just have exterminated several more populations of rattlesnakes in the name of science and knowledge. It is quite likely that the data they accumulated have little relevance except as comparative material to other dwindling populations that still exist. Their study populations have almost certainly been decimated for generations to come, if not permanently.

This is 1984, not 1884, and it seems to me that it is long past time to develop a genuine conservation ethic in the herpetological community at large. Decimation of populations of any species should not be tolerated. It is a well established fact that nearly all populations of wildlife of all groups are under constant assault from numerous threats. In the past, callous field biologists have not been included among those threats, but quite probably should have been.

We may 'legitimize' the exploitation of wildlife around the world by hungry, Third-World peoples because of their condition, but there is no excuse for this type of destruction by educated people—especially scientists in the pursuit of knowledge. Biologists are some of the most outspoken voices when it comes to commercial trade in wildlife, yet they seem to condone mass slaughter if it's in the name of Science. I say bull to that. Dead is dead, regardless of motivation.

This is only the latest study of its type I've noticed in the literature in recent years and each time I read of such numbers sacrificed, I'm appalled. If biologists of this type don't care any more than that about the living, propagating organisms than to kill them in obscene numbers, they should study rocks, or canned-goods on a supermarket shelf. If not the *living* animal, why are they interested in zoology to begin with? It is never a fair exchange to trade populations of living animals for sets of statistics or data bases! If that's the price of knowledge, the price is too high!

In closing, I would like to add that I feel the SSAR Conservation Committee has been negligent in this area. I believe that this whole issue should have been seriously addressed by that group long ago. Assuming the members of that group are truly concerned with the preservation of herptile populations, it is certainly within the realm of their responsibility to develop such a position for the Society, to make it publicly known, and to *encourage* compliance with specified guidelines.

JOSEPH DINARDO
16 Idlewild Road
Levittown, Pennsylvania 19057, U.S.A. ●

REPLY TO DINARDO'S LETTER

We completely agree with Mr. Dinardo's assertion that a genuine conservation ethic is necessary in the herpetological community and that "decimation of populations of any species should not be tolerated." We do support conservation of rattlesnakes, and, indeed, of all amphibians and reptiles, even though it apparently does not appear that way to some.

Assuming that it is acceptable to sacrifice a portion of a viable population of organisms for scientific research, we would answer the objections to our study by stating that we did not threaten the existence of any local population of snakes by our collections. Although numerous hibernacula were visited initially, only three were selected as representative sites within the study area for extensive collections. These three hibernacula were well suited for removal sampling because they were accessible and vulnerable to rattlesnake hunting that is prevalent in our area.

The hibernacula sampled represent three of about twenty known to us in the study area. The number of hibernacula within our study area (about 500 km^2) that are unknown or inaccessible probably is in the hundreds. In addition, the number of hibernacula within our study area is not an unusual local phenomenon. The extensive river systems with their rugged steep canyons and abundant talus and scree slopes in remote regions of northern and central Idaho contain the same ideal rattlesnake habitat that is found in our study area.

Not only were we sampling a small fraction of the hibernacula in the study area, but the three hibernacula where we collected were not decimated as Mr. Dinardo has suggested. Each of these populations contained hundreds of snakes. Our collecting certainly decreased but did not decimate the populations. The three sites were visited during the summers of 1983 and 1984 after all collections had stopped. All sites still had viable populations of snakes including gravid females. Only one population is in any danger of extinction. This is due to the fact that it is within the growth zone of a small town, and there are diligent but so far unsuccessful efforts now being made to exterminate the snakes.

Mr. Dinardo's "reasonable assumption that none of those visited hibernacula will any longer produce many snakes" is completely invalid. In fact, in addition to the three main sites, we visited five other dens during our study and obtained a total of 21 rattlesnakes. One of those dens (one with a small population) is the site of our current studies where about 150 rattlesnakes have been marked and released over the past three years. Three of the remaining four hibernacula have been visited since 1981, and snakes were seen at all in about the same numbers as they were during our study.

The number and size of rattlesnake populations in northern and central Idaho may seem unbelievable to people not familiar with the area. Several factors make rattlesnake populations much larger and more stable here than they apparently are in many parts of the country. To begin with, there is a tremendous

amount of rattlesnake habitat, much of which is totally uninhabited by people. Human impacts on rattlesnake populations, therefore, are greatly reduced. Secondly, the hibernacula have all been found in steep talus or scree slopes (up to 100 m or more in width, 10 m or more from top to bottom) that are difficult and often hazardous to traverse. Snakes are frequently warned of an approaching person due to shifting and tumbling rocks. Even when one manages to reach the snakes undetected, they are seldom fully exposed on the surface and readily escape into the porous talus. The snakes in talus cannot be dug out because more rocks will continually slough from above. Rattlesnakes in talus also are not readily exterminated by shooting, burning, or dynamiting. We know ranchers who have been attempting to exterminate a population of snakes for years by these methods with no apparent success. Apparently enough rattlesnakes can always escape to maintain the population.

The overall objective of our study was not to simply generate some data for comparative purposes but to carry out a long-term study (10-20 years) to determine those population and reproductive parameters of snakes that are seldom attempted. However, in the first phase of our study, we felt it was necessary to get certain baseline reproductive data that could best be obtained by sacrificing snakes. In the second phase of our ongoing study, our efforts are concentrated on marking individuals from one of the "other" hibernacula and monitoring movements, growth, and reproductive success.

The final point we would like to address is whether such a study as ours is the work of "callous field biologists." Certainly a biologist that threatened a population of organisms in order to generate data would be callous and unworthy of being a part of the scientific community. However, sacrificing animals "in the name of science" when there is a considerable margin of safety does not automatically make one callous and uncompassionate toward the animals being studied. This long-term study was initiated out of a keen interest and respect for rattlesnakes and not a desire for "quick" data.

We conclude by applauding Mr. Dinardo's concern and willingness to speak out for responsible scientific studies. We hope he and others around the country are convinced that rattlesnake populations in northern Idaho are as large and healthy in 1984 as they were before the start of our study.

EDITOR:

In an age of heightened environmental awareness, concern in the scientific community for protection of biologically vulnerable species (whether or not they may be officially listed as threatened or endangered) clearly has gained prominence in recent years. Despite this favorable attitude, certain lapses in our vigilance may occur. Such a case, I believe, is shown by a recent paper published in a respected herpetological journal (L. V. Diller and R. L. Wallace, 1984, Herpetologica 40:182-193) on the reproductive biology of the northern Pacific rattlesnake *(Crotalus viridis oreganus)* in which an apparently large number of individuals (387) was taken from three denning populations in Idaho.

My purpose here is not to question the findings of the study but rather to comment on the general conservation issues it raises and how to deal with these issues. There are two central problems: (1) the degree of depletion of the populations in the dens, and (2) the impact of identifying the locations of the dens.

Almost all vertebrate field biologists, including herpetologists, are aware of similar conservation issues in their particular localities involving their particular species, so it is not novel to cite cases of seasonal habitat use or behaviors which make a species vulnerable. Winter aggregations of bats in caves,

1984 INVENTORY AVAILABLE
&
REQUEST FOR INFORMATION FOR THE 1985 EDITION
INVENTORY OF LIVE REPTILES AND AMPHIBIANS IN CAPTIVITY

The Inventory of live Reptiles and Amphibians in Captivity, Current January 1, 1984 is a combined inventory of 212 reptile and amphibian collections, both public and private representing 12 countries. Published by the author. 1984 314 pp., $25.00 ($20.00 paperbound) plus $2.00 postage ($3.00 overseas).

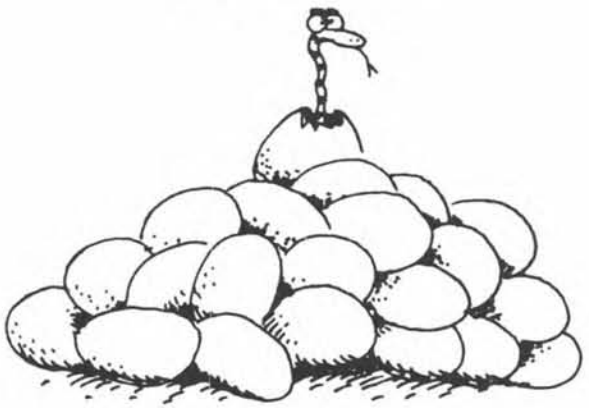
All institutions worldwide, holding live reptiles and/or amphibians are asked to submit inventories and breeding information current up to January 1st of each year. Private collectors are also welcomed to submit information, but emphasis is on those collections which have breeding potential, have had breeding success in the past, or hold species which are rare or difficult to obtain.

I am now preparing to receive information current as of January 1, 1985. If you keep live reptiles and/or amphibians in captivity, please respond with the information requested below.

(1) A complete inventory of all reptiles and amphibians held in your collection current as of January 1st. Sexes should be included and can be listed "male/female/unknown sex."

(2) A list of all species which bred and produced young during 1984, including numbers of young for each species.

(3) Any miscellaneous breeding information (use the information presented in the 1984 edition as a guide). Include detailed information for all species which you feel should be listed.



(4) Longevity records for any species which you think notable. Please include the number of years, months, days and indicate if the specimen is still living.

(5) A listing of any publications, including books, museum bulletins, journals, magazines, etc. with reference to reproduction in reptiles and amphibians. References pertaining to the care of individual species as well as more general articles relating to temperature, light cycle, hibernation, etc. are of interest.

Deadline for receipt of information is March 1st.

All orders and information should be sent to:

Frank L. Slavens
P.O. Box 30744
Seattle, Washington 98103.

concentrated nesting of sea turtles, and communal denning of rattlesnakes are but a few examples. Forty years ago in Utah, the well-known Woodbury den contained around five hundred Great Basin rattlesnakes but within twenty-five years the population had been reduced to a mere remnant of about two dozen snakes largely because the location of this den was revealed to numerous persons in the belief that such knowledge would promote conservation through education. After the word spread, however, it did not take long for human predation to virtually extinguish this once-spectacular aggregation.

As to the first problem raised by the Diller and Wallace study, it is difficult to assess the seriousness of removing 240 females (84 of which were sexually mature) over a four-year period because no information is available in the paper on the estimated total population sizes and the proportion of the female populations this number represents. On demographic grounds, a "take" of this magnitude may be detrimental in view of the late age of female maturity (4 to 6 years) and small mean litter size (5.5) of *C. v. oreganus* in Idaho. Nor do we know how likely it would be for immigration to help replenish the losses (i.e., how isolated these denning populations are from others). My impression, based on knowledge of the Utah *C. v. lutosus* den and current work on timber rattlesnake *(C. horridus)* dens, is that such a level of exploitation probably represents a significant depletion of the populations in these Idaho dens.

The second problem may well be the most serious for these denning colonies in the long run. Exact locations (distances and directions from towns, elevations), as well as publication of the local names of the dens, may ensure that these denning colonies will receive increased attention from snake hunters and unscrupulous collectors. It falls heavily upon those of us who serve as reviewers and editors of our journals to be aware of this problem and to urge deletion of information that may threaten the survival of vulnerable populations of amphibians and reptiles.
